About the cover design

The cover illustrations commemorate human ingenuity, including inventions and technological advances. Such technological developments often build on earlier inventions and achievements. Inventors, scientists, and engineers continue to develop new technologies and to refine older ones to make people's lives easier, more productive, and more enjoyable.

Preface

The World Book Encyclopedia, a publication of World Book, Inc., was first published in 1917 as an 8-volume set. The encyclopedia has been expanded many times through the years and now has 22 volumes. Throughout its publishing history, *World Book* has sought new and better ways to serve its readers. For a brief summary of *World Book*'s development, see the article **Encyclopedia** (History).

Aims and objectives

The editorial staff of *World Book* presents information from the vast reservoir of knowledge in the most accessible and usable form. The editors design *World Book* articles especially to meet the reference and study needs of students in elementary school, junior high school, and high school. *World Book* also serves as a general family reference tool. Librarians, teachers, and the general public likewise turn to *World Book* to satisfy their everyday reference needs.

Authority

At the heart of *World Book*'s editorial process is its Advisory Board, along with its other editorial advisers and consultants. These outstanding scholars and specialists include experts in such major academic fields as school administration, area studies, biological sciences, humanities, library science and services, physical sciences, and social sciences, as well as specialists in readability and curriculum development. These advisers and consultants are involved in the planning, production, and ongoing evaluation of *World Book*.

World Book engages more than 3,800 scholars and experts as contributors, authenticators, reviewers, and consultants. The name of the contributor or reviewer appears at the end of *World Book* articles. *World Book* advisers, consultants, and contributors are listed in the front of the "A" volume. The publishers of *World Book* maintain a large permanent staff of editors, artists, researchers, indexers, librarians, and various support personnel.

Selection of contents

An ongoing program of research and evaluation provides the editors with the data needed to help make decisions on the encyclopedia's contents. Two aspects of the program are particularly noteworthy:

The Classroom Research Project provides continuous testing of *World Book* in about 200 classrooms throughout the United States and Canada. Students use the latest edition of *World Book* and fill out cards to show what they looked up. More than 25,000 cards are analyzed annually, providing the editors with current information on the actual patterns of classroom use by students.

In addition to the Classroom Research Project, curriculum studies supply the editors with information about the topics studied in typical school systems for all grades from kindergarten through high school. An ongoing analysis of curriculum guides, national and state standards, and textbooks provides information on current, as well as new and emerging, school topics.

Other research helps shape distinctive features of *World Book*. For example, a unique research project uncovered data on how children read and interpret maps. The research findings resulted in principles of design that guide the development of *World Book* maps. Many special research studies have been carried out under the supervision of members of the *World Book* Advisory Board.

Presentation of information

World Book is organized so that readers may quickly find the information they are seeking. This is achieved through a single alphabetical arrangement of articles and entry cross-references, a carefully designed page and article format, and a comprehensive, single-volume index.

World Book uses a modified unit-letter arrangement of volumes. All entries that begin with the letter "A" are found in Volume A and so on throughout most of the set. In two instances, a single volume is not large enough to accommodate all the articles that start with the same letter, and the entries are divided between two volumes.

Most reference questions are answered by referring to Volumes 1 through 21, where the reader finds either an article or a cross-reference to such an article. If there is no article or cross-reference, the reader can turn to Volume 22, the Research Guide/Index. Thus, *World Book* provides the reader with both an extensive system of alphabetically arranged articles and cross-references, and a comprehensive, in-depth index.

All topics are arranged alphabetically, using the word-by-word system. For example, **Arab League** precedes **Arabesque**, and **New Mexico** appears before **Newark**. Thousands of cross-references form part of this alphabetical arrangement. They guide the reader to a subject or to some information that may be a part of another article, or that may appear as an alternate title. *See* and *See also* cross-references are included within many articles. A list of *Related articles* at the end of many *World Book* articles guides the reader to additional information in the encyclopedia.

World Book's page format is designed for maximum usefulness. Page numbers and guide words at the top of a page provide rapid access to subjects. Within articles, topics and subtopics stand out in boldface center headings and boldface side headings.

World Book's fivefold plan for major articles brings together five basic elements: (1) a complete story, (2) visual aids, (3) related articles, (4) an outline, and (5) questions.

1. The complete story gives readers a solid foundation of information about a subject.
2. A wide variety of visual aids clarifies meaning and reinforces learning. Photographs, drawings, paintings, maps, diagrams, charts, and graphs make information come alive.
3. A list of related *World Book* articles encourages readers to broaden their study of a subject.
4. An outline gives readers an overall view of the article and shows the interrelationship of its units.
5. Questions help readers review important information in the article. They are designed to reinforce understanding of the major areas of a topic.

Readability

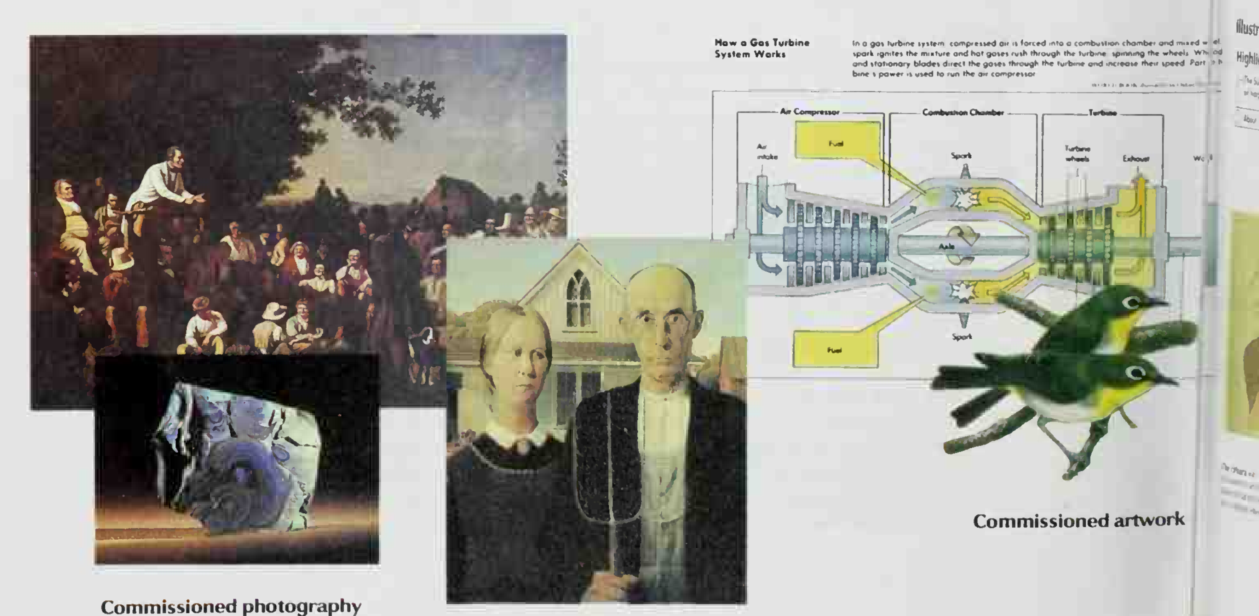
World Book editors present information in a clear, direct style that meets the most exacting standards of readability. The curriculum analysis and classroom research program help the editors design articles to be understandable at the age levels where they are most commonly used. Vocabulary is geared to the proper age group. For example, the **Mouse** article was written especially for younger children, and **Cell** was aimed at advanced readers. Many long articles are designed to present simpler concepts and reading levels at the beginning. These articles build toward more sophisticated concepts and reading levels toward the end. The **Leaf** article is an excellent example of this simple-to-more-complex approach.

In developing an article, the editor checks its vocabulary against a list of about 44,000 words created especially for *World Book* by its readability consultants.

World Book editors use words that can be understood at the grade level of the article, but they use technical terms where needed. Such words are defined immediately in the article, thus ensuring understanding and helping vocabulary development. In the **Moon** article, for example, the section on *The movements of the moon* uses the words *elliptical, perigee, apogee, synodic month,* and *sidereal month*. These words are printed in italics, and their

meanings are given in parentheses or defined within the context of the sentence in which they appear. Similar techniques are used throughout the set to define difficult words and clarify meanings.

Most major articles have undergone thorough readability analyses by *World Book*'s readability consultants and editors. Some of these articles have also been tested for comprehension by students at appropriate grade levels.



Illustrations and maps

Illustrations are combined with text in *World Book* to achieve the most effective communication of information. An illustration is placed close to the portion of subject matter that it is designed to clarify, supplement, or complement. *World Book* has more than 27,500 illustrations, over 24,000 in color. Many *World Book* illustrations were created exclusively for the encyclopedia by specially commissioned illustrators and photographers. For example, the color photographs in the **Mineral** article were obtained by a specially assigned photographer working with museum experts. Specialists in depicting nature subjects have illustrated such articles as **Animal, Bird**, **Flower**, **Insect**, **Spider**, and **Tree**.

World Book's treatment of the fine arts is exemplified by the **Painting** article. This 64-page article features reproductions of about 100 paintings from the world's leading museums and private collections. In addition, numerous biographies of noted artists are illustrated with color reproductions of their work.

In illustrating historical articles, **World Book** uses period art where appropriate. For example, the article **United States, History of the**, includes more than 20 pieces of art by such well-known artists as George Caleb Bingham, Currier and Ives, and Benjamin West. Illustrated time lines in such articles as **Classical music** and **Medicine** help place people and events in historical perspective.

Among the illustrative features of *World Book* is a Trans-Vision® unit that uses transparent color overlays to clarify an important subject. This visual technique is used in the **Human body** article to show both the details and the

Fine art reproduction

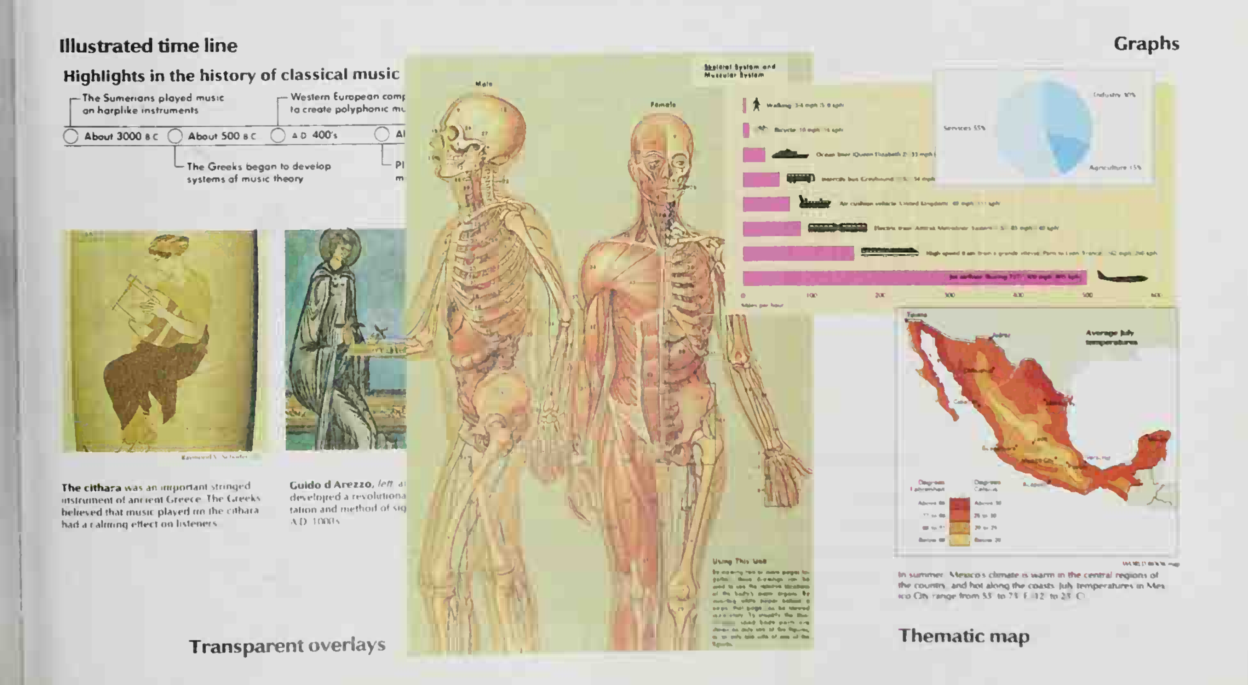
Technical diagram

Commissioned artwork

Commissioned photography

relationships of the human body's major systems.

World Book has more than 2,200 maps, all of them in color. The publisher conducts research that analyzes type size and placement, color, symbolization, captioning, scale, and other elements involved in map design. Design principles based on such research are incorporated in *World Book* maps. Examples of maps that use these principles are the thematic maps in articles on the states, provinces, major countries, and continents. These maps convey basic information on such topics as climate, economy, population distribution, and historical development.



Research aids

Many research aids have been built into *World Book*. These aids facilitate the search for information within *World Book* and assist the reader in finding information beyond the encyclopedia. These research aids appear both in the alphabetical volumes and in Volume 22, the Research Guide/Index.

Listings of *Related articles* at the end of many *World Book* articles lead the reader to additional, related information on the subject. For example, after reading the section *The Era of Expansion (1831-1870)* in the **American literature** article, a reader might want to learn more about Emily Dickinson, Walt Whitman, and other poets of the period. The *Related articles* section at the end of the **American literature** article includes an alphabetical listing of articles on the writers of this period.

The *Additional resources* heading that follows more than 1,500 articles in *World Book* leads the user to further reading on the subject. These lists of books have been carefully selected—often with the assistance of the experts who wrote or reviewed the articles—to represent the most current, balanced scholarship. In some instances, the books have been grouped on two levels, with Level I books being easier to use than Level II books.

An instructional section called *A Student Guide to Better Writing, Speaking, and Research Skills* in Volume 22 gives students practical, easy-to-understand guidance in carrying out everyday school assignments. It includes writing tips and advice on preparing different types of written reports; advice on prepar-

ing and delivering an oral report; and detailed information on using the library and tapping other reference sources.

Revision program

An encyclopedia must be up to date if it is to serve the best interests of its users. A revised edition of *World Book* is published each year. Each edition reflects up-to-date information and the latest changes in educational viewpoints. Every subject area is under continuing surveillance. The annual revision program is never confined to a single area or to certain volumes. Thousands of pages are revised or updated each year.

To keep *World Book* owners abreast of world events, *The World Book Year Book*, an annual supplement, is published each January. The version available to libraries and schools is called *World Book's Year in Review*. Dated for the year of issue, the supplement reviews the events of the previous year. It includes special articles on a broad spectrum of topics, and it reports major news developments, alphabetically listed, to update *World Book*. It also publishes a selection of new or revised major articles from the current edition of *World Book*. A three-year cumulative index provides ready access to information in the current and previous two editions of *The Year Book (Year in Review)*.

Physical format

The high goals of *World Book*'s editorial processes also characterize its manufacturing processes. *World Book* is printed on modern web offset presses, custom-built for the encyclopedia. *World Book*'s presses allow the use of color throughout the set. The paper used in *World Book* is especially manufactured to achieve the best results from color printing.

The text type used in *World Book*—World Book Modern—was created exclusively for *World Book* by Hermann Zapf, an internationally renowned type designer. His specifications for the text type have been incorporated into a page format that facilitates readability and the search for information.

World Book's attractive and practical binding materials were selected for their durability, dirt resistance, and high scuff resistance.

Tests at every stage of production during the printing and binding processes are conducted at the press facilities and in *World Book*'s Product Production Department.

Electronic versions

The content of *The World Book Encyclopedia* is also available in online versions on a subscription basis. In addition, *World Book* is available on CD-ROM (Compact Disc Read-Only Memory).

The editors

How to use World Book

World Book is a tool for learning—a general encyclopedia that tells about people, places, things, events, and ideas. It provides accurate information that is easy to understand and easy to find.

You may come to your encyclopedia for the answer to a particular question, such as "How high is a badminton net?" or "What is the population of Haiti?" Or you may seek general information for a school assignment. Parents and young people, when they plan together for the future, often come to *World Book* to find out about the possibilities in various careers. And, of course, many people like simply to explore *World Book,* letting one topic lead them to another. Browsing or skimming through the encyclopedia is an enjoyable way to pick up interesting information on many subjects.

All articles, generally called *entries* in *World Book,* are arranged alphabetically, volume by volume and subject by subject. Included in this alphabetical arrangement are also thousands of *entry cross-references.* Cross-references are explained in detail later in this section.

All entries that begin with the letter "A" are found in Volume A, everything that starts with "B" is in Volume B, and so on throughout most of the set. In some cases, entries that start with two or more consecutive letters of the alphabet are combined in one volume. Or, a single volume may not be large enough to hold all the articles that start with the same letter. In such cases, entries starting with the same letter are divided between two volumes. For example, *World Book* articles that begin with the letter "C" are contained in two volumes—C to Ch and Ci to Cz.

In most instances, *World Book's* alphabetical arrangement of articles and cross-references will enable you to find the information you are seeking. However, if you do not find the information, turn to Volume 22, the Research Guide/Index. Its more than 150,000 index entries provide access to the wealth of information in *World Book.*

Volume 22 also includes an instructional section titled *A Student Guide to Better Writing, Speaking, and Research Skills.* This feature has been designed to help students assigned a written or oral report.

For information on using the index, see Volume 22, the Research Guide/Index.

Assigned a written or oral report? Turn to *A Student Guide to Better Writing, Speaking, and Research Skills* in Volume 22 for advice on how to go about it.

The word-by-word arrangement

The alphabetical system used in *World Book* is the same system used in arranging a telephone directory and the card catalogs of books in most libraries. This *word-by-word* arrangement puts entries that have titles beginning with a short word ahead of titles that have the short word as the first letters of a longer word. For example, you will find **Ant bear** and **Ant lion** ahead of **Antabuse** and **Antarctic.** Similarly, all place names starting with **New** are together, and they are followed by names that have **New** as their first letters. New Jersey comes before New Mexico, which precedes **New York.** Following them are such entries as **Newark** and **Newfoundland.**

Exceptions to this rule are certain foreign proper names and English names of foreign origin that include a preposition or an article. For example, **De Gaulle** is alphabetized as if it were one word because **De** is a preposition. Likewise, **El Dorado** is alphabetized as one word because **El** is an article. Biographies of people whose names begin with **Mac,** such as **MacDonald,** are listed alphabetically under **Mac.** Names that begin with **Mc,** such as **McKinley,** are listed alphabetically under **Mc,** following entries beginning **Ma** and **Mb.**

Guide words

At the top of most pages is a *guide word*. The purpose of the guide word is to help you locate quickly the entry you are seeking. On a left-hand page, the guide word (or words) may be the title of the first entry that appears in the first column of that page. Or, the guide word may be the title of an article that is continued from a preceding page, if the continuation takes up the whole first column. On a right-hand page, the guide word is the title of the last article on that page.

Let us say your question is: "What is a labor movement?" First, select the *key word*—the most important word—in the question: "Labor." In most cases, this word will be the same as the entry in *World Book*. So, look for **Labor** in Volume L. Start leafing through Volume L, noting the guide words on the tops of the pages.

Leaf forward until you see guide words that begin with "Lab," such as **Labor, Department of.** If you come upon such guide words as **Labrador** or **Labyrinth**, you know you must go back to find the **Labor movement** article in its alphabetical place. Finding an entry in *World Book* is very much like finding a word in a dictionary.

Entry cross-references

Thousands of *cross-references* are important aids to finding information in *World Book*. There are several types of cross-references. The principal type is the *entry cross-reference*. These cross-references appear in heavy type—the same as article titles—and are included in *World Book's* alphabetical arrangement.

Some entry cross-references provide you with the titles of topics that can be found in the set under other names. For example, in Volume B you will find the entry **Benares.** See **Varanasi.** That entry directs you to the **Varanasi** article because the city of Benares is also known as Varanasi.

Other entry cross-references tell you in what section of an article to find current information. If you want information about belugas, you look up that entry in its proper alphabetical place in Volume B. You will find the entry cross-reference: **Beluga.** See **Whale** (Belugas and narwhals). Then you would turn to the **Whale** article and leaf through it until you come to the section entitled **Belugas and narwhals.**

---

4 **Labor movement**

Labor movement is a term that refers to the efforts of workers as a group to improve their economic position. The movement consists chiefly of attempts by labor unions to promote the welfare of wage earners. But political parties and other groups have also played a part in the labor movement.

Before the development of labor unions, individual laborers had almost no voice in determining their wages, hours, or working conditions. There was a plentiful supply. The union sends men and women called organizers to persuade workers to join.

Most unions insist on being the sole representative of a particular group of employees. They do not want to share the privilege of representing the workers with any other group. This practice is called the *principle of exclusive jurisdiction*. The National Labor Relations Board conducts secret-ballot elections at firms to determine which union workers want, if any.

---

246 **Beluga**

Beluga. See Whale (Belugas and narwhals).

Bemba is a term used to describe the language and culture of a large ethnic group in Central Africa. The Bemba language and culture are both called *Icibemba*. The name for the people who belong to this ethnic group is *Ababemba*. The traditional territory of the Bemba people, in northern Zambia, is called *Ulubemba*.

The Bemba language belongs to the Bantu family, which includes hundreds of other African languages, such as Swahili and Zulu. Bemba is the most widely spoken language in Zambia. About 4 million people speak Bemba or related dialects as their first language. Many other people speak it as a second or third language.

Most Bemba people in rural areas are farmers. They grow cassava, maize, millet, peanuts, sweet potatoes, and other crops. Fishing and occasional hunting add to their diet. In cities, Bemba people work in a variety of professions. Bemba families are *matrilineal* (related through the female line). Many Bemba families live as a large *extended family*, in which parents, children, grandparents, and other relatives share a home. The extended family plays a major role in people's lives, providing security and help with farm and household chores.

The Bemba people were once part of the ancient Luba Empire in what is now Congo (Kinshasa). They migrated to northern Zambia in the mid-1600's. The Bemba *Chitimukulu* (paramount chief) is the traditional ruler within Bemba territory. Today, the Chitimukulu also has a strong advisory role within the Zambian national government. Debra Spitulnik and Alexander Raymond Makasa Kasonde

See also Bantu; Luba; Zambia.

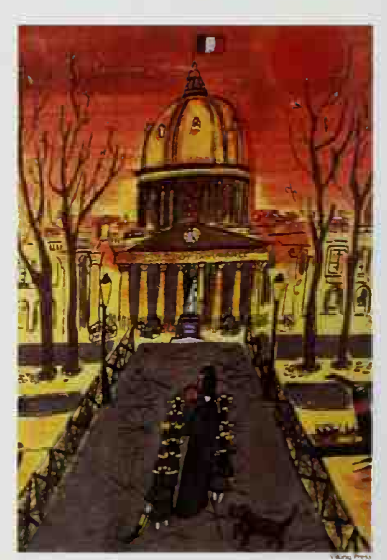
Bemelmans, *BEHM uhl muhnz,* **Ludwig** (1898-1962), was an American author and artist. He became best known for his children's books, especially six picture books about a young girl in Paris named Madeline. Bemelmans won the 1954 Caldecott Medal for his charming and colorful illustrations for *Madeline's Rescue* (1953). He began the series with *Madeline* (1939).

Bemelmans was born in a section of the Tyrol province of Austria now part of Italy, and moved to the United States in 1914. He became a U.S. citizen in 1918. Bemelmans also wrote stories and novels for adults. His nonfiction for adults includes a humorous autobiographical account of his experiences in the U.S. Army, *My War with the United States* (1937). A selection of his writings was published in 1985, after his death, as *Tell Them It Was Wonderful*. Jill P. May

Ben Bella, Ahmed (1919-) was the first president of the Republic of Algeria. He helped lead the revolt that freed Algeria from French rule. He served as president from 1963 to 1965, when he was overthrown by the army commander, Houari Boumedienne. Ben Bella was then held prisoner by the Algerian government until 1980, following Boumedienne's death in 1978.

Ben Bella was born in Marnia (now Maghnia), Algeria. He served in the French Army during World War II (1939-1945). He later became a leader in the Algerian independence movement. In 1949, he led a raid on the Oran post office and stole more than 3 million francs to help finance the movement. The French jailed him, but he escaped. In 1954, Ben Bella helped found the Algerian National Liberation Front (FLN). The French recaptured him in 1956. They released him in March 1962. In July, France gave Algeria its independence. Ben Bella then took control of the country. He was elected president in 1963. Kenneth J. Perkins

See also Algeria (Independence).



Ben-Gurion, *behn GOO rih uhn,* **David** (1886-1973), served as Israel's first prime minister after it became independent in 1948. He served as prime minister and minister of defense from 1948 to 1953 and from 1955 to 1963.

During the Suez crisis of 1956, Ben-Gurion ordered the Israeli invasion of the Gaza Strip and Sinai Peninsula. Later, Israeli forces withdrew at the request of the United Nations.

Ben-Gurion was born David Green in Plonsk, Russia (now in Poland). He settled in Palestine in 1906. By 1919, he was a Zionist leader, working for creation of a Jewish state in Palestine (see **Zionism**). In 1930, he founded the Mapai (Israel Workers' Party). He was a secretary-general of the *Histadrut* (General Federation of Labor) from 1921 to 1935.

As chairman of the Executive of the Jewish Agency for Palestine from 1935 to 1948, Ben-Gurion directed all Jewish affairs in the country. His activities ranged from land development and settlement of immigrants to secret activities against Arabs and the British. Ben-Gurion retired in 1963. Ellis Rivkin

See also **Israel** (History).

Viking Press

A Ludwig Bemelmans drawing from his book *Madeline's Rescue*, the 1954 Caldecott Medal winner, shows Madeline and 11 other little girls taking their daily walk in Paris with their teacher.

Cross-references within the text

In addition to the entry cross-references, *World Book* provides many cross-references within the text of articles and at the end of articles. These "see" and "see also" cross-references direct you to particular maps, charts, pictures, or articles and sections of articles for additional information on material that you have just read. Good examples of this kind of cross-reference are "see **Zionism**" found in the **Ben-Gurion, David** article and the See also cross-reference at the end of the **Ben Bella, Ahmed** article.

Article headings

We have told you about finding articles in *World Book*. Now, look at some of the aids that help you find information quickly *within* most of the articles. Turn to the **Tree** article. You will notice this long article is divided into sections, each with its own *head* or *heading*—words in large type that tell you what information will be found in the section—for example:

How a tree grows

Every section has been divided into *subsections*, each with a *subhead* or *subheading* in heavy type that pinpoints particular kinds of information. For example, under the heading *How a tree grows*, you will find these subheads: How seeds sprout into trees; How leaves make plant food; How trees grow taller; and How trunks and branches grow thicker. All of these heads and subheads lead you to the particular kinds of information you might be seeking if you did not wish to read the entire Tree article.

Note also that the color diagrams in the article have special headings that serve a similar purpose, for example: How a tree reveals its history. Many medium-length and short articles in *World Book* are also divided into sections that have heads and subheads, but of course some articles are so short that they do not require separate sections.

Captions

The illustrations in *World Book* all have *captions*—special text which usually starts with heavy type that quickly identifies the subject. Captions give information that clarifies or adds to the information given in the article. A caption will be found close to an illustration.

ject, you can throw a life preserver, a board, or any other object that will float and support the swimmer

Swimming kicks and strokes

Swimmers move their legs, feet, arms, and hands in certain ways to propel themselves through the water easily and quickly. The movements of the legs and feet are called *kicks*. These movements combined with movements of the arms and hands are called *strokes*.

The basic kicks. Swimmers use four types of kicks

---

418 **Tree**

How a tree grows

Most trees begin life as a seed. The young tree that develops from this seed is called a *seedling*. After a tree reaches a height of 6 feet (1.8 meters) or more and its trunk becomes 1 to 2 inches (2.5 to 5 centimeters) thick, it is called a *sapling*. Many trees reach a height of more than 100 feet (30 meters). Some old trees have trunks more than 10 feet (3 meters) in diameter.

Trees need great amounts of water. A large apple tree in full leaf may absorb 95 gallons (360 liters) from the soil daily. Most of the water goes to the leaves. On a sunny summer day, some trees move water up through their trunks at the rate of 3 feet (91 centimeters) per minute. A tree's wood is about half water.

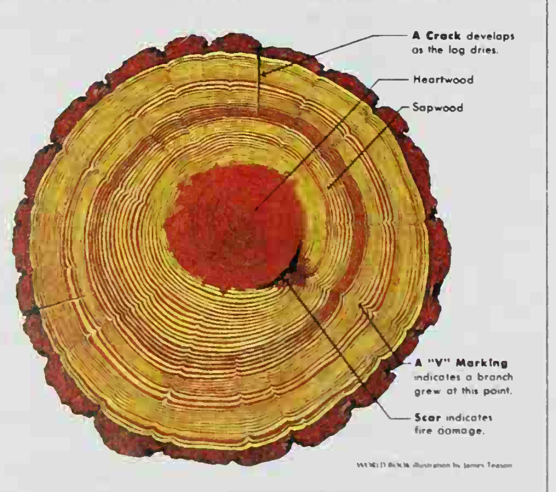
How seeds sprout into trees. A seed contains parts that develop into the trunk and roots of a tree. It also has one or more cotyledons and a supply of plant food. After a seed has left the parent tree, it rests for a while on the ground. Water, air, and sunshine help the seed *germinate* (begin to grow). The part of the seed that develops into the trunk points upward toward the sunlight. As the seed absorbs water, the root part swells and bursts through the seed's shell. As the root grows, it pushes down into the soil. The food stored in the seed nourishes the tree. As the root begins to soak up water from the soil, the trunk begins to develop leaves.

How leaves make plant food. As a leaf develops, it gets sap from the roots. It also absorbs carbon dioxide from the air. The leaf uses the energy of sunlight to change the sap and carbon dioxide into sugar, a process called *photosynthesis*. The sugar provides food for the trunk, branches, and roots. During photosynthesis, the leaves also produce oxygen and release it into the atmosphere. See **Leaf** (How a leaf makes food).

How trees grow taller. Trees grow taller only at the tips of their trunk and branches. Each year, the tips of the trunk and of each branch develop a *bud*. The bud contains a tiny leafy green stem called a *shoot*. The bud is wrapped in a protective covering of *bud scales*. After a period of rest, the buds swell and open. The shoots that were inside the buds begin to grow and so make the trunk and branches taller. Another type of bud grows on the sides of the trunk and branches. These buds contain a shoot that develops into a leaf bearing *twig* after the bud opens. As a twig grows larger, it becomes another branch of the tree. Some tree buds develop into flowers. Still others develop into twigs that bear both leaves and flowers. In warm climates, trees produce buds frequently during the year or continue to grow without forming buds. In colder climates, trees produce buds only in the summer. These buds rest in winter and open after warm weather arrives in spring.

Trees without branches—cycads, most palms, and tree ferns—grow somewhat differently. For example, a young palm tree does not grow taller for a number of years. Its short trunk thickens and produces more and larger leaves each year. After the trunk and crown reach adult size, the tree begins to grow taller. The trunk stays about the same thickness for the rest of the tree's life.

How trunks and branches grow thicker. The trunk and branches of a broadleaf or needleleaf tree grow thicker as long as the tree lives. The cambium tissue just underneath the inner bark causes this thickening. It uses the sugar produced by the leaves to make new plant tissue. On its outside, the cambium makes new phloem, or inner bark, and on its inside, new xylem, or wood.



Wood consists largely of *cellulose*, a tough substance made from sugar. The xylem has two kinds of wood—*sapwood* and *heartwood*. The wood nearest the cambium is the sapwood. It is living wood and contains the tiny pipelines that carry sap. In tropical climates, the

How a tree reveals its history

Most trees in temperate regions grow a layer of wood each year. After such a tree has been cut down, the layers can be seen as rings in the trunk. These *annual rings* reveal the tree's life story. The pine log in this drawing has 72 annual rings, showing that the tree lived for 72 years

Narrow center rings indicate that other trees shaded the young tree, depriving it of moisture and sunlight

Wider rings on the log's lower side after the 30th year show that the tree was slightly bent in this direction. The tree then began to grow more wood on this side than on the other to keep from falling. Most rings after the 38th year are wider than the center rings. This indicates that many surrounding trees had been removed, giving the tree more moisture and sunlight. Differences in the width of rings after the 38th ring were caused mainly by varying amounts of rainfall from year to year.

Other research aids

On this page, a number of special research aids found in *World Book* are shown. If you make good use of them, they will facilitate your search for information. Browse through the set and you will find these special features in many articles. They have been developed to help you get the most out of *World Book.*

Facts in brief

Capital: London
Official language: English.
Area: 50,352 sq. mi. (130,410 km²), *Greatest distances*—north-south, about 360 mi. (579 km); east-west, about 270 mi. (435 km). *Coastline*—about 1,150 mi. (1,851 km).
Elevation: *Highest*—Scafell Pike, 3,210 ft. (978 m) above sea level. *Lowest*—Great Holme Fen, near the River Ouse in Cambridgeshire, 9 ft. (2.7 m) below sea level.

Facts in brief tables are found in state, province, country, continent, and many other articles. They provide information at a glance.

Horse terms

Bronco, or **Bronc,** is an untamed Western horse.
Colt, technically, is a male horse 4 years old or less. However, the word colt is often used for any young horse.
Crossbred means bred from a sire of one breed and a dam of another.
Dam is the mother of a foal.
Filly is a female horse 4 years old or less.

Tables of terms present information that defines certain words or phrases used in discussing specialized or highly technical topics.

Important dates in Kennedy's life

1917 (May 29) Born in Brookline, Mass.
1940 Graduated from Harvard University.
1941-1945 Served in the U.S. Navy during World War II.
1946 Elected to the U.S. House of Representatives.
1952 Elected to the U.S. Senate.
1953 (Sept. 12) Married Jacqueline Lee Bouvier.

Tables of important dates are included in many articles. They provide quick reference to outstanding events in the history of a topic.

Related articles listings at the end of many articles direct the reader to additional, related information in *World Book.*

Key to pronunciation

The World Book Encyclopedia provides pronunciation for many unusual or unfamiliar words, either with the article title or where the word appears in the text. In the pronunciation, the words are divided into syllables and respelled according to the way each syllable sounds. The syllables appear in *italic* letters. For example, here is an article title along with the respelled pronunciation for it:

Antibiotic, *AN tee by AHT ihk*

The syllable that bears the greatest emphasis when the word is spoken appears in capital letters *(AHT)*. If the word is long enough to have a syllable that receives secondary emphasis, that syllable appears in small capitals *(AN)*. More than one pronunciation appears for words that have several accepted pronunciations in English, for words that have distinctive pronunciations in other languages, and for names that have distinctive local pronunciations (such as **Arkansas River,** *AHR kuhn SAW or ahr KANS zuhs)*.

World Book uses a number of diacritical marks and special characters to indicate the correct spellings for many words and names in languages other than English. These marks have various meanings, according to the languages in which they are used. An acute accent mark (´) over an *e* in a French word indicates that the *é* is pronounced *ay*. An acute accent mark over an *e* in a Spanish word indicates that the syllable containing the *é* bears the main emphasis in the word. The accented characters may look difficult, and some of them represent sounds that are hard for English-speaking people to make. But the respelled pronunciation normally makes the sounds clear, as in **Dvořák,** *DVAWR zhahk,* or **Lódz,** *looj or lahdz*.

The pronunciation key at the right shows how common word sounds are indicated by diacritical marks in *The World Book Dictionary* and by respelling in *The World Book Encyclopedia*. The key also shows examples of the *schwa,* or unaccented vowel sound. The schwa is represented by ə.

Letter or mark	As In	Respelling		Example

Canemaker, John, M.F.A. Film animator; author, *Treasures of Disney Animation Art.*

Cangelosi, V. E., Ph.D. Prof. of Quantitative Methods, Dean of the Junior Division, and Director of Developmental Education, Louisiana State Univ.

Cannistraro, Philip V., Ph.D. Prof. of History, Drexel Univ.

Cannon, Patrick J., M.B.A. President, EarthRise Tethered Balloon Systems and Engineering.

Cantril, Albert H., Ph.D. Former Fellow, Institute of Politics, Harvard Univ.

Cao, Tian Yu, Ph.D. Asst. Prof. of Philosophy, Boston Univ.

Capelli, Gregory M., Assoc. Prof. of Biology, College of William and Mary.

Caplan, Arthur, Ph.D. Director, Center for Bioethics, Univ. of Pennsylvania.

Capps, Walter Holden, Ph.D. Former Prof. of Religious Studies, Univ. of California, Santa Barbara.

Captain, George J. Former Chief, Eastern Shawnee.

Carbo, Toni, Ph.D. Dean and Prof., School of Information Sciences, Univ. of Pittsburgh.

Cardona, George, Ph.D. Graduate Group Chair, Dept. of Linguistics, Univ. of Pennsylvania.

Carey, George W., Ph.D. Prof. of Government, Georgetown Univ.

Carey, James W., Ph.D. CBS Prof. of International Journalism, Graduate School of Journalism, Columbia Univ.

Carico, James E., Ph.D. Dean, School of Sciences, Lynchburg College.

Caringer, Denise L., B.A. Executive Editor, Home Decorating and Design, Better Homes and Gardens Books.

Carlin, Norman F., Ph.D. Lecturer on Biology, Harvard Univ.

Carlson, Ann D., D.L.S. Prof., Graduate School of Library and Information Science, Dominican Univ.

Carlson, John, Ph.D. Prof., Dept. of Agriculture, Western Illinois Univ.

Carlson, W. Bernard, Ph.D. Assoc. Prof., Technology, Culture, and Communication, Univ. of Virginia.

Carlson, William H., Ph.D. Prof. of Horticulture, Michigan State Univ.

Carlton, Charles, Ph.D. Prof. of History, North Carolina State Univ.

Carlton, James T., Ph.D. Dir., Maritime Studies Program, Williams College, Mystic Seaport.

Carpenter, Kenneth, Ph.D. Paleontologist, Denver Museum of Natural History.

Carpenter, Robert H., Ph.D. Former geological consultant.

Carpenter, Thomas P., Ph.D. Prof. of Curriculum and Instruction and Director, National Center for Improving Student Learning and Achievement in Mathematics and Science, Univ. of Wisconsin.

Carr, Anne E., Ph.D. Prof. of Theology, Univ. of Chicago Divinity School.

Carr, Dale C., M.A. Chief Music Librarian, Public Library, Groningen, Netherlands.

Carr, Michael H., Ph.D. Geologist, U.S. Geological Survey.

Carr, Stephen H., Ph.D. Assoc. Dean of Engineering, Northwestern Univ.

Carraway, Kermit L., Ph.D. Prof., Dept. of Cell Biology, Univ. of Miami School of Medicine.

Carriker, Robert C., Ph.D. Prof. of History, Gonzaga Univ.

Carroll, Bob, B.A. Executive Director, Pro Football Researchers Association.

Carroll, Holbert N., Ph.D. Prof. of Political Science Emeritus, Univ. of Pittsburgh.

Carroll, John L., M.D. Prof., Pediatrics and Physiology; Dir., Pediatric Pulmonary Division, Arkansas Children's Hospital.

Carroll, Peter N., Ph.D. Author, *It Seemed Like Nothing Happened: America in the 1970s.*

Carson, Clayborne, Ph.D. Prof. of History and Director, Martin Luther King, Jr., Papers Project, Stanford Univ.

Carson, Culley C., M.D. Prof. and Chairman of Urology, Univ. of North Carolina.

Carson, Robert B., Ph.D. Prof. Emeritus of Economics and Business, State Univ. of New York, Oneonta.

Carter, Dan T., Ph.D. Education Foundation Prof. of History, Univ. of South Carolina.

Carter, Lisle Carleton, Jr., LL.B. Attorney at Law.

Carter, William E., Ph.D. Former Research Geodesist, National Oceanic and Atmospheric Admin.

Cartwright, Donald G., Ph.D. Prof. of Geography, Univ. of Western Ontario.

Case, Karl E., Ph.D. Prof. of Economics, Wellesley College.

Case, William B., Ph.D. Prof. of Physics, Grinnell College.

Caserio, Marjorie C., Ph.D. Prof. Emeritus of Chemistry and Biochemistry, Univ. of California, San Diego.

Cashman, Katharine V., Ph.D. Assoc. Prof. of Geological Sciences, Univ. of Oregon.

Caskey, C. Thomas, M.D. Senior Vice President, Human Genetics and Vaccines Discovery, Merck Research Laboratories.

Cassara, Catherine, Ph.D. Assoc. Prof., Dept. of Journalism, Bowling Green State Univ.

Cassell, Carol A., Ph.D. Director, Institute of Sexuality Education and Equity.

Cassidy, David, Ph.D. Assoc. Prof. of Natural Science, Hofstra Univ.

Castellanos, F. Xavier, M.D. Prof. of Child and Adolescent Psychiatry and Director, Institute for Pediatric Neuroscience, New York Univ. School of Medicine.

Catanese, Anthony James, Ph.D. President and Prof., Florida Atlantic Univ.

Catania, Peter J., Ph.D. Program Chair, Industrial and Petroleum Systems Engineering, Univ. of Regina.

Cateforis, David, Ph.D. Asst. Prof. of Art History, Univ. of Kansas.

Cates, Ward Mitchell, Ed.D. Prof., College of Education, Lehigh Univ.

Cathey, James E., Ph.D. Prof. of Germanic Languages and Literatures, Univ. of Massachusetts, Amherst; coauthor, *Old Icelandic.*

Causey, Virginia E., Ph.D. Assoc. Prof., Dept. of History, Columbus State University.

Cauvin, Jean-Pierre, Ph.D. Prof. of French, Univ. of Texas.

Cech, John, Ph.D. Director, Center for the Study of Children's Literature and Media, Univ. of Florida.

Ceci, Lynn, Ph.D. Former Assoc. Prof., Anthropology, Queen's College, City Univ. of New York.

Cerulo, Karen A., Ph.D. Prof. of Sociology, Rutgers, the State Univ. of New Jersey.

Cezairliyan, Ared, Ph.D. Former Research Physicist, National Inst. of Standards and Technology.

Chalmers, David, Ph.D. Distinguished Service Prof. of History, Univ. of Florida.

Chalupnik, James D., Ph.D. Prof. Emeritus, Dept. of Mechanical Engineering, Univ. of Washington.

Chamberlain, David S., Ph.D. Former Prof. of English, Univ. of Iowa.

Chambers, Mindy, A.B. Political Editor, *The*

(Olympia, WA) *Olympian.*

Chambers, Mortimer, Ph.D. Prof. Emeritus of History, Univ. of California, Los Angeles.

Chambers, William Nisbet, Ph.D. Former Prof. of History, Washington Univ.

Chamblee, Theresa S., M.S. Senior Scientist, Corporate Research and Development, The Coca-Cola Company.

Champlin, Charles, A.B. Arts Editor Emeritus, *Los Angeles Times*; Author, *Hollywood's Revolutionary Decade.*

Chandler, David P., Ph.D. Prof. of History, Monash Univ.; author, *A History of Cambodia.*

Chaney, William A., Ph.D. George McKendree Steele Prof. of Western Culture, Lawrence Univ.

Chang, Parris H., Ph.D. Former Director, Center for East Asian Studies, Pennsylvania State Univ.

Channell, David F., Ph.D. Prof. of Historical Studies, Univ. of Texas, Dallas.

Chapman, Graham P., Ph.D. Prof., Dept. of Geography, Lancaster Univ.

Charbonneau, Hubert, Ph.D. Prof. Emeritus of Demography, Univ. of Montreal.

Charles, C. M., Ph.D. Prof. of Teacher Education, San Diego State Univ.

Charles, Robert W., Ph.D. Group Leader, Univ. of California, Los Alamos National Laboratory.

Charlesworth, J. H., Ph.D. Prof. of New Testament Language and Literature; Director, Dead Sea Scrolls Project, Princeton Theological Seminary.

Chase, Philander D., Ph.D. Editor, *The Papers of George Washington.*

Chatfield, Charles, Ph.D. Emeritus Prof. of History, Wittenberg Univ.

Chatterjee, Sankar, Ph.D. Prof. of Geology and Curator of Paleontology, Texas Tech Univ.

Chavarria, Jesús, Ph.D. Chairman and Publisher, *Hispanic Business* magazine.

Chege, Michael, Ph.D. Director, Center for African Studies, Univ. of Florida.

Cheng, Richard M. H., F.I.Mech.E. Prof. Emeritus of Mechanical Engineering, Concordia Univ.

Cherchi, Paolo, Ph.D. Prof. of Italian Literature, Univ. of Chicago.

Cherkauer, Douglas S., Ph.D. Prof. of Geosciences, Univ. of Wisconsin, Milwaukee.

Cherny, Robert W., Ph.D. Prof. of History, San Francisco State Univ.

Chertow, Marian R., Ph.D. Dir., Industrial Environmental Management Program, Yale School of Forestry and Environmental Studies.

Chesick, John P., Ph.D. Prof. Emeritus of Chemistry, Haverford College.

Chikeka, Charles O., Ph.D. Assoc. Prof. of History, Morgan State Univ.

Child, Jois C., Ph.D. Former Asst. Prof. of Geography, Eastern Washington Univ.

Childress, Dudley S., Ph.D. Director, Rehab. Engineering Research Program and Prosthetics Research Lab., Northwestern Univ. Medical School.

Childs, William R., Ph.D. Assoc. Prof. of History, Ohio State Univ.

Chisholm, James J., M.S. Engineering Manager, Hewlett Packard Co.

Cho, S. Henry, M.S. Prof. of Karate, St. John's Univ.; Pres., World Council of Martial Arts, Inc.

Chow, Kai-wing, Ph.D. Assoc. Prof. of History and East Asian Languages and Cultures, Univ. of Illinois, Urbana-Champaign.

Christ, Carol Tecla, Ph.D. Prof. of English, Univ. of California, Berkeley.

Christensen, Norman L., Jr., Ph.D. Prof. of Ecology, Nicholas School of the Environment and Earth Sciences, Duke Univ.

Christiansen, John B., Ph.D. Prof. of Sociology, Gallaudet Univ.

Christianson, Eric Howard, Ph.D. Assoc. Prof. of History, Univ. of Kentucky.

Chuman, Dwight, B.A.J. Former Editor, *Gambling Times* magazine.

Church, Andrew, Ph.D. Prof. of Geography, School of the Environment, Univ. of Brighton.

Churchill, James E. Free-lance writer.

Cicale, Annie, M.F.A. Professional calligrapher.

Clancy, Lou Former Managing Editor, *The Toronto Star.*

Clapp, John M., Ph.D. Prof. of Finance and Real Estate, Univ. of Connecticut.

Clapp, Stephen, M.Sc. Dean and Violin Faculty Member, Juilliard School.

Clark, Alan F., Ph.D. Division Chief, Magnetic Technology Division, National Inst. of Standards and Technology.

Clark, C. B., Ph.D. Former Prof. of American Indian Studies, California State Univ.

Clark, Charles E., Ph.D. Emeritus Prof. of History, Univ. of New Hampshire.

Clark, Clifford E., Jr., Ph.D. Prof. of History; Hulings Prof. of American Studies, Carleton College.

Clark, Edward W., Ph.D. Prof. of English, Winthrop Univ.

Clark, J. C. D., Ph.D. Prof., Hall Center for the Humanities, Univ. of Kansas.

Clark, J. Derrell, D.Sc. Former Prof. of Medical Microbiology, Univ. of Georgia.

Clark, Kenneth E., Ph.D. Smith Richardson Senior Scientist, Center for Creative Leadership.

Clark, Larry V., Ph.D. Asst. Prof., Indiana Univ.

Clark, Michael P., B.A. Reader Advocate, *The* (Jacksonville) *Florida Times-Union.*

Clark, Nancy L., Ph.D. Assoc. Prof. of History, California Polytechnic State Univ.

Clark, Robert E., Ph.D. Former Asst. Prof. of Geography, Univ. of Northern Iowa.

Clark, Robert Sadler, B.A. President, United States Surfing Committee.

Clark, Scott, B.A. Dir., Bonsai Clubs International.

Clark, Terry Nichols, Ph.D. Prof. of Sociology, Univ. of Chicago.

Clark, Thomas D., Ph.D. Author, *A History of Kentucky.*

Clark, W. Dennis, Ph.D. Assoc. Prof. of Botany, Arizona State Univ.

Clark, William W., Ph.D. Prof. of Art, Queens College and Grad. Center, City Univ. of New York.

Clauson, Barbara L., M.S. Adjunct Curator, Univ. of Kansas Natural History Museum.

Claybaugh, Charles C., B.S. Publisher, (Brigham City, UT) *Box Elder News Journal.*

Clayton, Lawrence A., Ph.D. Chairman, Dept. of History, Univ. of Alabama.

Clayton, Paula J., M.D. Chairman, Department of Psychiatry, Univ. of Minnesota, Twin Cities Campus.

Cleeton, David L., Ph.D. Prof. and Chair, Economics Dept., Oberlin College.

Clemens, Diane Shaver, Ph.D. Prof. of History, Univ. of California, Berkeley.

Clemens, Paul G. E., Ph.D. Prof. of History, Rutgers, the State Univ. of New Jersey.

Clemens, Walter C., Jr., Ph.D. Prof. of Political Science, Boston Univ.; Associate, Harvard Univ. Davis Center for Russian Studies.

Clements, Kendrick A., Ph.D. Prof. of History, Univ. of South Carolina.

Clemmer, Dan O., M.L.S. Head Librarian, U.S. Dept. of State Library.

Clendenning, John, Ph.D. Prof. of English, California State Univ., Northridge.

Clerc, Daryl G., Ph.D. Research Scientist, T/J Technologies, Inc.

Cliff, Eugene M., Ph.D. Reynolds Metals Prof., Aerospace & Ocean Engineering, Virginia Polytechnic Institute and State Univ.

Clifton, Robert G., B.S. Former Managing Director, American Brush Manufacturers Association.

Cliver, Dean O., Ph.D. Prof., Food Safety, School of Veterinary Medicine, Univ. of California-Davis.

Clonts, Howard A., Jr., Ph.D. Director, Environmental Institute and Water Resources Research Institute, Auburn Univ.

Cloos, Mark, Ph.D. Prof. of Geological Sciences, Univ. of Texas, Austin.

Clout, Hugh D., Ph.D. Prof. of Geography, Univ. College London.

Clum, James A., Ph.D. Director, Manufacturing Engineering Program, Univ. of Detroit Mercy.

Coakley, Timothy N., M.A. Copy Editor, *The* (Schenectady, NY) *Daily Gazette.*

Coale, Samuel Chase, Ph.D. Prof. of English, Wheaton College.

Cobb, William E., Ph.D. Prof. Emeritus of Economics, West Virginia Graduate College.

Coble, Harold D., Ph.D. Former Prof. of Crop Science, North Carolina State Univ.

Cochran, Robert C., Ph.D. Prof. of Animal Science, Kansas State Univ.

Cockroft, Irene, Dip. History. Author, *Books of the Month.*

Coffman, Edward M., Ph.D. Emeritus Prof. of History, Univ. of Wisconsin, Madison.

Coffman, John Edwin, Ph.D. Former Assoc. Prof. of Geography, Univ. of Houston.

Cohen, Daniel, B.J. Writer.

Cohen, Jacob, M.A. Prof. and Chairman, Dept. of American Studies, Brandeis Univ.

Cohen, Jeremy, Ph.D. Former Assoc. Prof. of Communication, Stanford Univ.

Cohen, S. Marc, Ph.D. Prof. of Philosophy, Univ. of Washington.

Cohen, Sarah Blacher, Ph.D. Prof. of English, State Univ. of New York, Albany.

Cohen, Steve, B.A. Senior Contributing Editor, *Ski* magazine.

Cohen, Stuart E., M.Arch. Architect; Prof. of Architecture, Univ. of Illinois, Chicago.

Cohn, Martin A., M.D. Director, Sleep Disorders Center of Southwest Florida, Naples.

Cohn, Sherman L., LL.M. Prof. of Law, Georgetown Univ.

Cole, David E., Ph.D. President, Center for Automotive Research, The Altarum Institute.

Cole, Francis T., Ph.D. Former Physicist, Fermi National Accelerator Laboratory.

Cole, Hugh M., Ph.D. Author, *The Ardennes Campaign.*

Cole, I. W., M.S.J. Former Dean, Medill School of Journalism, Northwestern Univ.

Cole, Madison B., Jr., Ph.D. Former Chief, Electron Microscopy Laboratory, Hines Veterans Administration Hospital.

Coleman, Dorothy S., B.A. Author, *Lenci Dolls*; coauthor, *The Collector's Encyclopedia of Dolls.*

Coleman, Evelyn Jane, M.A. Coauthor, *The Collector's Encyclopedia of Dolls.*

Coleman, J. M., Ph.D. Boyd Prof., Coastal Studies Institute, Louisiana State Univ.

Coleman, Kenneth, Ph.D. Prof. Emeritus of History, Univ. of Georgia.

Coles, William E., Jr., Ph.D. Prof. Emeritus of English, Univ. of Pittsburgh.

Colgan, Charles T., J.D. Executive Vice-President, National Steeplechase Association.

Collier, Virginia P., Ph.D. Prof. of Bilingual/Multicultural/ESL Education, George Mason Univ.

Collins, Arlene R., Ph.D. Assoc. Prof. of Microbiology, State Univ. of New York-Buffalo School of Biomedical Sciences.

Collins, K. K., Ph.D. Assoc. Prof. of English, Southern Illinois Univ., Carbondale.

Collins, Nigel Editor in Chief, London Publishing.

Coltoff, Philip, M.S.W. Executive Director, The Children's Aid Society.

Colvin, Howard A., Ph.D. Project Manager, New Solutions Polymer and Catalyst Research, Goodyear Tire & Rubber Co.

Comanor, William S., Ph.D. Prof. of Economics, Univ. of California, Santa Barbara.; Prof. of Health Services, Univ. of California, Los Angeles.

Combs, Jerald A., Ph.D. Chair and Prof. of History, San Francisco State Univ.

Commins, Stephen K., Ph.D. Director, Global Analysis and Policy, World Vision International.

Concepcion, Anne-Marie, M.A. President, Seneca Design and Consulting.

Condon, Richard H., Ph.D. Prof. Emeritus of History, Univ. of Maine, Farmington.

Conger, Clement Ellis, D.H.L. Former Chairman, Fine Arts Committee, U.S. Dept. of State.

Friedman, Ann, Ph.D. Education Specialist, J. Paul Getty Museum.

Fritz, Harry W., Ph.D. Chair, Dept. of History, Univ. of Montana.

Frodin, Joanna H., Ph.D. Vice President, Federal Reserve Bank of Philadelphia.

From, Milton, Ph.D. Asst. Prof. of Physics, Western Washington Univ.

Fry, Edward S., Ph.D. Prof. of Physics, Texas A&M Univ.

Frye, B. E., Ph.D. Provost and Vice President for Academic Affairs, Emory Univ.

Frye, Richard Nelson, Ph.D. Prof. Emeritus of Iranian Studies, Harvard Univ.

Frykenberg, Robert Eric, Ph.D. Prof. Emer., History and South Asian Studies, Univ. of Wisconsin.

Fuhrmann, Joseph T., Ph.D. Prof. of History, Murray State Univ.

Fujita, T. Theodore, Sc.D. Prof. Emeritus of Meteorology, Univ. of Chicago.

Fukuta, Norihiko, Ph.D. Prof. of Meteorology, Univ. of Utah.

Fulghum, Julia E., Ph.D. Prof., Dept. of Chemistry, Kent State Univ.

Fulton, E. Kaye, B.A. Senior Writer, *Maclean's* magazine.

Fulton, Robert, Ph.D. Prof. Emeritus of Sociology, Univ. of Minnesota, Twin Cities Campus.

Furnas, David W., M.D. Clinical Prof. of Surgery, College of Medicine, Univ. of California, Irvine.

Fusfeld, Daniel R., Ph.D. Prof. Emeritus of Economics, Univ. of Michigan.

Fuson, Karen Connors, Ph.D. Prof. of Education, Northwestern Univ.

G

Gabel, Christopher R., Ph.D. Historian, U.S. Army Command and General Staff College.

Gable, Dan, B.S. Former Wrestling Coach, Univ. of Iowa.

Gable, John A., Ph.D. Executive Director, Theodore Roosevelt Association.

Gadwood, Robert C., Ph.D. Senior Scientist, Pharmacia & Upjohn.

Gager, Wyvolyn, B.A. Former Editor in Chief, *Gleaner Publications,* Kingston, Jamaica.

Gagliano, Joseph A., Ph.D. Prof. of Latin American History, Loyola Univ. of Chicago.

Gailey, Harry A., Ph.D. Prof. of History and Coordinator of African Studies, San Jose State Univ.

Gait, Robert I., Ph.D. Curator Emeritus of Mineralogy, Royal Ontario Museum, Toronto.

Gallagher, Joan S., Ph.D. Research Assoc., Pathology/Immunology, Univ. of Cincinnati.

Gallagher, Rachel, B.A. Author, *Games in the Street.*

Gallis, Paul E., Ph.D. Section Head, Europe and Eurasia Foreign Affairs, Defense, and Trade Division, Congressional Research Service.

Galloway, J. H., Ph.D. Prof. of Geography, Univ. of Toronto.

Galvin, Antoinette B., Ph.D. Research Assoc., Prof., Institute for the Study of Earth, Oceans, and Space, Univ. of New Hampshire.

Gandy, Joan W., B.A. Former Managing Editor, *The Natchez* (MS) *Democrat.*

Gangel, Kenneth O., Ph.D. Former Academic Dean, Dallas Theological Seminary.

Gantt, Elisabeth, Ph.D. Research Biologist, Smithsonian Institution.

Gantz, Nelson M., M.D. Chairman, Dept. of Medicine and Chief, Division of Infectious Diseases, Pinnacle Health Hospitals.

Garbarino, Merwyn S., Ph.D. Prof. Emerita of Anthropology, Univ. of Illinois, Chicago.

Garber, Eugene K., Ph.D. Former Prof. of English, State Univ. of New York, Albany.

Garber, Lawrence L., Ph.D. Prof. of Chemistry, Indiana Univ., South Bend.

Garcia, Homer D. C., Ph.D. Vice Provost for Academic Planning, Baylor Univ.

Gardin, Julius M., M.D. Prof. of Medicine, Div. of Cardiology, Univ. of California Irvine Medical Ctr.

Gardner, Lloyd C., Ph.D. Prof. of History, Rutgers, the State Univ. of New Jersey.

Garfield, Robert, Ph.D. Assoc. Prof. of History, DePaul Univ.

Garfinkel, Irwin, Ph.D. Mitchell I. Ginsberg Prof. of Contemporary Urban Problems, Columbia Univ. School of Social Work.

Garibaldi, Louis E., Dir., New York Aquarium.

Garmon, Lucille B., Ph.D. Prof. of Chemistry, State Univ. of West Georgia.

Garnes, Sara, Ph.D. Assoc. Prof. of English, Ohio State Univ.

Garnick, Marc B., M.D. Clinical Prof., Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School.

Garretson, Peter P., Ph.D. Assoc. Prof. of History, Florida State Univ.

Garrett, Charles L., B.S. President, Garrett Electronics, Inc.

Garrison, David L., Ph.D. Asst. Program Director, Ocean Sciences Div., National Science Foundation.

Garrow, David J., Ph.D. Author, *Bearing the Cross: Martin Luther King, Jr., and the Southern Christian Leadership Conference;* winner, Pulitzer Prize for Biography or Autobiography, 1987.

Garzke, William H., Jr., M.S. Staff Naval Architect, Gibbs & Cox, Inc.

Gass, Susan M., Ph.D. Prof. of English, Michigan State Univ.

Gates, William C., Jr., M.A. Curator and Historian, Ohio Historical Society.

Gaud, Susan M., Ph.D. Director, External Technology, Kraft Foods.

Gauthreaux, Sidney A., Jr., Ph.D. Prof. of Zoology, Clemson Univ.

Gavrilas, Mirela, Ph.D. Asst. Prof., Dept. of Materials and Nuclear Engineering, University of Maryland, College Park.

Gavrilovich, Peter Deputy Nation/World Editor, *Detroit Free Press;* author, *The Detroit Almanac: 300 Years of Life in the Motor City.*

Gedzelman, Stanley David, Ph.D. Prof. of Meteorology, City College of New York.

Geerken, John H., Ph.D. Prof. of History, Scripps College.

Geherin, David, Ph.D. Prof. of English, Eastern Michigan Univ.

Geiger, Gordon H., Ph.D. Consultant, T. P. McNulty & Associates.

Geist, Valerius, Ph.D. Prof. Emeritus of Environmental Sciences, Univ. of Calgary.

Gelfand, Lawrence E., Ph.D. Prof. Emeritus of History, Univ. of Iowa.

Gelles, Richard J., Ph.D. Prof. of Social Welfare and Director, Doctoral Program, School of Social Work, Univ. of Pennsylvania.

Gellman, Barton, M.L.H. Military Correspondent, *The Washington Post.*

Genovese, E. N., Ph.D. Prof. and Chair of Classics and Humanities, San Diego State Univ.

Genovese, Michael A., Ph.D. Loyola Chair of Leadership, Loyola Marymount Univ.

Genoways, Hugh H., Ph.D. Prof., Univ. of Nebraska State Museum, Univ. of Nebraska, Lincoln.

Gentry, Alwyn H., Ph.D. Former Senior Curator, Missouri Botanical Garden.

George, David B., B.S. Director, Technology, Kennecott Utah Copper Corp.

Hansen, Ellen R., Ph.D. Asst. Prof., Dept. of Social Sciences, Emporia State Univ.

Hansen, James R., Ph.D. Alumni Prof./Historian for National Aeronautics and Space Administration, Auburn Univ.

Hansen, Katherine, Ph.D. Assoc. Prof. of Geography, Montana State Univ.

Hansen, William F., Ph.D. Prof. of Classical Studies and Folklore, Indiana Univ.

Hansma, Paul, Ph.D. Prof. of Physics, Univ. of California, Santa Barbara.

Hanson, Stephen E., Ph.D. Assoc. Prof., Univ. of Washington.

Hapeman, Cathleen J., Ph.D. Research Chemist, Agriculture Research Service, U.S. Dept. of Agriculture.

Hardcastle, David P., Ph.D. Writer and historian.

Harden, Lydia Dixon, B.S. Former Managing Editor, *Music City News.*

Harder, Leland, Ph.D. Former Prof. of Practical Theology, Mennonite Biblical Seminary.

Hardy, Grant, Ph.D. Asst. Prof. of History, Univ. of North Carolina, Asheville.

Hargis, B. M., Ph.D. Prof. and Director, Poultry Health Research Laboratory, Center of Excellence for Poultry Science, Univ. of Arkansas, Fayetteville.

Harik, Elsa Marston, M.S. Writer.

Harik, Iliya, Ph.D. Prof. of Political Science, Indiana Univ.

Harington, C. R., Ph.D. Curator of Quaternary Zoology Emeritus, Canadian Museum of Nature.

Harmon, Daniel P., Ph.D. Prof. and Chairman, Dept. of Classics, Univ. of Washington.

Harmon, Pat Curator-Historian, College Football Hall of Fame.

Harmon, William, Ph.D. Prof. of English, Univ. of North Carolina.

Harper, Craig, B.S.J. Former News Editor, *News North,* Yellow Knife, N.W. Ter.

Harper, J. E., Ph.D. Research Leader, Agricultural Research Service, U.S. Dept. of Agriculture.

Harper, Kimball T., Ph.D. Prof. Emeritus of Botany and Range Science, Brigham Young Univ.

Harran, Marilyn J., Ph.D. Prof. of Religion and History, Chapman Univ.

Harries, Keith D., Ph.D. Contributing author, *The Geography of Oklahoma.*

Harrington, John A., Jr., Ph.D. Assoc. Prof. of Geography, Kansas State Univ.

Harris, Alan A., M.D. Hospital Epidemiologist, Prof., Asst. Chairman of Internal Medicine, Rush-Presbyterian-St. Luke's Medical Center, Chicago.

Harris, Jules E., M.D. Prof. of Medicine, Rush Univ.

Harris, Leslie, Ph.D. Pres. Emer., Memorial Univ.

Harris, Michael H., Ph.D. Prof. of Library Science, Univ. of Kentucky.

Harris, Michael W., B.A. Asst. Editor, *Houseboat* magazine.

Harris, Neil, Ph.D. Prof. of History, Univ. of Chicago.

Harrison, Frederick W., Ph.D. Prof. of Biology, Western Carolina Univ.

Harrison, Gregory B., B.A.J. Vice President, Communications, American Motorcyclist Assn.

Harrison, Michael M., Ph.D. Former Assoc. Director, Graduate Institute of International Studies, Geneva, Switzerland.

Hart, Lynn W., Ph.D. Physicist, Principal Staff, The Johns Hopkins Univ. Applied Physics Laboratory.

Hartl, Daniel L., Ph.D. Prof. of Organismic and Evolutionary Biology, Harvard Univ.

Hartlein, Richard A., M.S.M.E. Program Manager, Underground Systems, National Electric Energy Testing Research and Applications Center, Georgia Institute of Technology.

Hartman, Ann, D.S.W. Dean, Smith College School for Social Work.

Hartman, J. P., Ph.D. Former Prof. of Engineering, Univ. of Central Florida, Orlando.

Hartman, Marvis E., Ph.D. Director, Automotive Technologies Europe, PPG Industries.

Hartman, Mary S., Ph.D. Director, Institute for Women's Leadership, Rutgers, the State Univ. of New Jersey; author, *Victorian Murderesses.*

Hartmann, Ernest, M.D. Prof. of Psychiatry, Tufts Univ. School of Medicine; Director, Sleep Disorders Center, Newton-Wellesley Hospital.

Hartwick, Brian, Ph.D. Assoc. Prof. of Biological Sciences, Simon Fraser Univ.

Harvey, Neil F., Ph.D. Assoc. Prof., Dept. of Government, New Mexico State Univ.

Harvey, Maurice, B.A. Air Commodore, Royal Air Force, retired; author, *Gibraltar.*

Harvey, Robert R., M.L.A. Prof. of Landscape Architecture, Iowa State Univ.

Harwell, Mark A., Ph.D. Director, Center for Marine and Environmental Analyses, Univ. of Miami.

Haselkorn, Robert, Ph.D. F. L. Pritzker Distinguished Service Prof. of Molecular Genetics and Cell Biology, Univ. of Chicago.

Haskett, James P. Former Managing Editor, *Lethbridge* (AB) *Herald.*

Hassler, Kevin, B.A. Managing Editor, *Enid* (OK) *News & Eagle.*

Hastings, Harold M., Ph.D. Prof. and Chairperson of Mathematics and Assoc. Dean, Hofstra Univ.

Hatch, Ronald B., Ph.D. Assoc. Prof. of English, Univ. of British Columbia.

Hathaway, Bradford A., B.S. Former Special Sections Editor, *The* (New Bedford, MA) *Standard Times.*

Hatzenbuehler, Ronald L., Ph.D. Prof. of History, Idaho State Univ.

Hauser, Richard J., Ph.D. Director of Graduate Programs, Creighton Univ.

Havard, William C., Jr., Ph.D. Former Prof. of Political Science, Vanderbilt Univ.

Haveman, Robert H., Ph.D. Prof. of Economics, Univ. of Wisconsin, Madison.

Havens, Murray Clark, Ph.D. Prof. of Political Science, Texas Tech Univ.

Haverdink, William H., M.S.E.M. Staff Research Engineer, General Motors Research Laboratories.

Haverstock, Nathan A., A.B. Affiliate Scholar, Oberlin College.

Hawley, Ellis W., Ph.D. Prof. of History, Univ. of Iowa.

Hayes, Denis, J.D. President and CEO, Bullitt Foundation.

Hayes, Mary Eshbaugh, B.A. Contributing Editor and Columnist, *The Aspen* (CO) *Times.*

Hayward, Jane, Ph.D. Former Curator, Cloisters, Metropolitan Museum of Art, New York City.

Hazel, Fred, B.A. Editor Emeritus and Columnist, New Brunswick Publishing, Saint John.

Head, James W., III, Ph.D. Prof. of Geological Sciences, Brown Univ.

Heard, Andrew D., Ph.D. Assoc. Prof., Political Science Dept., Simon Fraser Univ.

Hearn, M. F., Ph.D. Prof. of Fine Arts and Director of Architectural Studies, Univ. of Pittsburgh.

Heath, James Edward, Ph.D. Prof. of Physiology and Biophysics, Univ. of Illinois.

Heckman, Timothy M., Ph.D. Prof. of Physics and Astronomy, Johns Hopkins Univ.

Hedgecoe, John, Dr.R.C.A. Photographer and author.

Hedquist, Valerie Lind, Ph.D. Asst. Prof. of Art, Central College, Pella, Iowa.

Hedrick, Philip W., Ph.D. Prof. of Biology, Arizona State Univ.

Heginbotham, Stanley J., Ph.D. Former Chief, Foreign Affairs and National Defense Div., Congressional Research Service, Library of Congress.

Hehr, John G., Ph.D. Prof. of Geosciences and Assoc. Dean, J. William Fulbright College of Arts and Sciences, Univ. of Arkansas, Fayetteville

Heidenreich, Conrad E., Ph.D. Prof. of Geography, York Univ.

Heidt, Gary A., Ph.D. Prof. and Chair, Dept. of Biology, Univ. of Arkansas, Little Rock.

Heilbrun, Margaret, M.L.S., M.A. Library Director, The New-York Historical Society

Heiman, Michael K., Ph.D. Assoc. Prof. of Geography and Environmental Studies, Dickinson College.

Heinrich, Bernd, Ph.D. Prof. of Biology, Univ. of Vermont.

Heitman, J. A. Former Executive Director, Professional Secretaries International.

Heitmann, John A., Ph.D. Assoc. Prof. of History, Univ. of Dayton.

Helfrick, Albert, Ph.D. Prof., Aeronautical Science Dept., Embry-Riddle Aeronautical Univ.

Hellen, J. A., D.Phil. Senior Lecturer, Dept. of Geography, Univ. of Newcastle upon Tyne.

Hellickson, Martin L., Ph.D. Assoc. Prof. of Bioresource Engineering, Oregon State Univ.

Helmer, William J., M.A. Senior Editor, *Playboy.*

Helms, Christine Moss, D.Phil. Author, *Cohesion of Saudi Arabia: Evolution of Political Identity* and *Iraq: Eastern Flank of the Arab World.*

Helms, Joseph M., M.D. Founding President, American Academy of Medical Acupuncture.

Helms, Ronald N., Ph.D. Prof. of Architectural Engineering, North Carolina Agricultural and Technical State Univ.; lighting consultant; expert witness.

Hemingway, Sam News Columnist, *Burlington* (VT) *Free Press.*

Henahan, John F., B.S. Science writer.

Henderson, David E., Ph.D. Prof. of Chemistry, Trinity College.

Hendler, Nelson H., M.D., M.S. Clinical Director, Mensana Clinic.

Hendricks, Lewis T., Ph.D. Prof. and Extension Specialist, Forest Products, Univ. of Minnesota, Twin Cities Campus.

Hendrickson, Chris, Ph.D. Prof. of Civil and Environmental Engineering, Carnegie Mellon Univ.

Henneman, John Bell, Ph.D. History Bibliographer, Princeton Univ.

Hennessey, William J., Ph.D. President and Director, Chrysler Museum of Art.

Henning, Basil D., Ph.D. Coauthor, *Crises in English History, 1066-1945.*

Henning, C. Randall, Ph.D. Research Assoc., Institute for International Economics.

Henry, Edward O., Ph.D. Prof. of Anthropology, San Diego State Univ.

Henry, Richard W., Ph.D. Prof. of Physics, Bucknell Univ.

Hentoff, Nat, B.A. Columnist, *Washington Post* and *Village Voice.*

Hepner, George F., Ph.D. Prof. of Geography, Univ. of Utah.

Herbert, Harry John, M.Sc. Wildlife Biologist, Zimbabwe Forestry Commission.

Herbert, Victor, J.D. Prof. of Medicine, Mount Sinai and Bronx Veterans Affairs Medical Centers.

Hermalyn, Gary D., Ed.D. Executive Director, Bronx County Historical Society; Editor of the Bicentennial of the United States Constitution Series.

Hermann, Donald H. J., Ph.D. Prof. of Law and Philosophy and Director, Health Law Institute, DePaul Univ.; author, *The Insanity Defense: Historical, Philosophical and Legal Perspectives.*

Hermann, William J., Jr., M.D. Dir., Clinical Laboratories, Memorial Hospital-Memorial City.

Hernon, Joseph Martin, Jr., Ph.D. Prof. of History, Univ. of Massachusetts, Amherst.

Herr, Edwin L., Ed.D. Distinguished Prof. of Education and Assoc. Dean for Graduate Programs, Research, and Technology, College of Education, Pennsylvania State Univ.

Herring, George C., Ph.D. Prof. of History, Univ. of Kentucky.

Herron, Ron, A.B.J. City Editor, (Frankfort, KY) *State Journal.*

Hersey, G. L., Ph.D. Prof. of the History of Art, Yale Univ.

Hershberg, Theodore, Ph.D. Director, Center for Greater Philadelphia; Prof. of Public Policy and History, Univ. of Pennsylvania.

Hertsgaard, Doris F., Ph.D. Director of Research, D H Research.

Herzstein, R. E., Ph.D. Carolina Distinguished Prof. of History, Univ. of South Carolina.

Hess, Andrew C., Ph.D. Prof. of Diplomacy, Fletcher School of Law and Diplomacy, Tufts Univ.

Hess, David F., Ph.D. Assoc. Prof. of Geology, Western Illinois Univ.

Hesse, Mark B., M.A. President, The American Mountain Foundation.

Hester, Thomas R., Ph.D. Prof. of Anthropology, Univ. of Texas, Austin.

Heydebrand, Wolf, Ph.D. Prof. of Sociology, New York Univ.

Hickey, Donald R., Ph.D. Prof. of History, Wayne State College.

Higgins, Lynn A., Ph.D. Prof. of French and Comparative Literature, Dartmouth College.

Highwater, Jamake Author; Arts Critic-at-large, *The Christian Science Monitor;* Founder and President, Native Land Foundation.

Hildebrand, Kurtis R., B.A. Asst. Managing Editor, *Nevada Appeal.*

Hildebrandt, Jack, Ph.D. Prof. of Physiology, Biophysics and Medicine, Univ. of Washington.

Hildesley, C. Hugh Executive Vice President, Sotheby's.

Hill, Andrew, Ph.D. Prof. of Anthropology, Yale Univ.

Hill, David T., Ph.D. Prof. of Southeast Asian Studies, Murdoch Univ.

Hill, James A., M.D. Prof. of Clinical Orthopedic Surgery, Northwestern Univ. Medical School.

Hill, James E., Ph.D. Chief, Building Environment Division, Natl. Inst. of Standards and Technology.

Hillary, Sir Edmund P., LL.D. Explorer and mountain climber; author, *High Adventure;* first to reach the summit of Mount Everest.

Hillson, C. J., Ph.D. Prof. Emeritus of Botany, Pennsylvania State Univ.

Hilt, Richard L., Ph.D. Prof. of Physics, Colorado College.

Hindman, Sandra L., Ph.D. Prof. of Art History, Northwestern Univ.

Hinman, Alan R., M.P.H. Director, National Center for Prevention Services, Centers for Disease Control and Prevention.

Hirsch, Edward, Ph.D. Prof. of English, Univ. of Houston.

Hirsch, Rick, B.S. Deputy City Editor, *The Miami* (FL) *Herald.*

Hirschfeld, Sue Ellen, Ph.D. Prof. of Geological Sciences, California State Univ., Hayward.

Hirschhorn, Joel S., Ph.D. President, Hirschhorn and Associates.

Hirsh, Richard F., Ph.D. Prof., Virginia Polytechnic Institute and State Univ.

Hirshman, Carol A., M.D. Prof. of Anesthesiology and Vice Chair for Research, Columbia Univ. College of Physicians and Surgeons.

Hitchcock, Bert, Ph.D. Hargis Prof. of American Literature, Auburn Univ.

Hobbs, Ray D., B.A. Deputy Managing Editor, (Little Rock) *Arkansas Democrat-Gazette.*

Hobbs, Richard R., M.S.A. Physics Teacher, Anne Arundel City (MD) Schools; author, *Marine Navigation.*

Hoberman, Robert D., Ph.D. Assoc. Prof., Dept. of Linguistics, State Univ. of New York, Stony Brook.

Hobson, Burton H., B.A. President and Editorial Director, Sterling Publishing Co.

Hocutt, Charles H., Ph.D. Ichthyologist, Center for Environmental and Estuarine Studies, Univ. of Maryland.

Hodgetts, J. E., F.R.S.C. Prof. Emeritus of Political Science, Univ. of Toronto.

Hodgetts, Richard M., Ph.D. Prof., Florida International Univ.

Hofferth, Sandra L., Ph.D. Senior Research Assoc., Urban Institute.

Hoffman, Cyrus M., Ph.D. Adjunct Prof. of Physics, Los Alamos National Laboratory.

Hoffman, Darleane Christian, Ph.D. Chemistry Prof., Graduate School, Univ. of California, Berkeley; Nuclear Chemist, Lawrence Berkeley National Laboratory

Hoffman, M. Peter, Ph.D. Prof. of Animal Science, Iowa State Univ.

Hoffmann, Peter, Ph.D. Fellow of the Royal Society of Canada; Prof. of History, McGill Univ.

Hoffmann, Richard J., Ph.D. Prof. of Zoology and Genetics, Iowa State Univ.

Hoffmeister, Werner, Ph.D. Prof. of German and Comparative Literature, Dartmouth College.

Hogan, Edward Patrick, Sr., Ph.D. Asst. Vice President, South Dakota State Univ.; State Geographer for South Dakota.

Hogg, R., Ph.D. Prof. of Mineral Processing and Geo-Environmental Engineering, Pennsylvania State Univ.

Hoh, LaVahn G., M.F.A. Prof. of Drama, Univ. of Virginia.

Holland, James C., Ph.D. Prof. of History, Shepherd College.

Hollister, C. Warren Prof. of History, Univ. of California, Santa Barbara.

Holloway, C. M. Journalist.

Holmes, A. William, M.D. Prof. of Medicine, Univ. of California, San Francisco.

Holmes, Johnny B., Ph.D. Prof. of Physics, Christian Brothers Univ.

Holmes, Kim R., Ph.D. Vice President, Dir., The Kathryn and Shelby Cullom Davis Institute for International Studies, The Heritage Foundation.

Holscher, Louis M., Ph.D. Prof. and Chair, Mexican American Studies, San Jose State Univ.

Holt, Michael F., Ph.D. Prof. of History, Univ. of Virginia.

Howe, Gordon Vice President, Howe Enterprises; aothor, *Hockey, Here's Howe!*

Howe, Herbert M., Ph.D. Emer. Prof. of Classics and Integrated Liberal Studies, Univ. of Wisconsin.

Howe, Russell Warren, License es-lettres. Writer.

Howell, David L., Ph.D. Assoc. Prof. of East Asian Studies, Princeton Univ.

Howell, Roger, Jr., D.Phil. Former Prof. of History, Bowdoin College.

Howse, Robert, B.A. Editor in Chief, *The Halifax* (NS) *Chronicle-Herald*.

Hoyt, Reginald A., Senior Vice President, Conservation and Science, Philadelphia Zoo.

Hoyt, Robert D., Ph.D. Prof. of Biology, Western Kentocky Univ.

Hoyt, Robert S., Ph.D. Aothor, *Europe in the Middle Ages*.

Hsu, Immanuel C. Y., Ph.D. Prof. of History, Univ. of California, Santa Barbara.

Hubbard, Paul, Ph.D. Prof. of History Emeritus, Arizona State Univ.

Hubbell, John T., Ph.D. Director, Kent State Univ. Press.

Huddleston, Ellis W., Ph.D. Prof. of Entomology, New Mexico State Univ.

Hudecki, Michael S., D.Sc. Executive Officer, Biological Sciences, State Univ. of New York, Buffalo.

Hudson, Charles, Ph.D. Prof. of Anthropology, Univ. of Georgia.

Hudson, John C., B.Sc. Former Regional Manager, Land Transportation, Public Works Canada.

Hudson, Michael C., Ph.D. Acting Dir., Center for Contemporary Arab Studies, Georgetown Univ.

Huey, Raymond B., Ph.D. Prof. of Zoology, Univ. of Washington.

Hufbauer, Gary, Ph.D. Reginald Jones Senior Fellow, Institute for International Economics.

Hufbauer, Karl, Ph.D. Prof. of History, Univ. of California, Irvine.

Huff, Jerome J., Jr., B.A. Managing Editor, (Fort Smith, AR) *Southwest Times Record*.

Huffines, Marion Lois, Ph.D. Assoc. Vice President, Academic Affairs, Bucknell Univ.

Huffman, Carl A., Ph.D. Assoc. Prof. of Classics, DePauw Univ.

Hughes, George R., M.S. Former Vegetable Crops Specialist and Specialist-in-Charge, Dept. of Horticulture Science, North Carolina State Univ.

Hughes, Robert M. President, Hughes Sports Television.

Hulse, James W., Ph.D. Prof. of History, Univ. of Nevada, Reno.

Hume, Stephen, B.A. Columnist-at-large, *Vancouver* (BC) *Sun*; author, *Ghost Camps*.

Humphris, Susan E., Ph.D. Senior Scientist, Woods Hole Oceanographic Institotion.

Hunkins, Francis P., Ph.D. Prof. of Education, Curricolum, Social Stodies, Univ. of Washington.

Hunner, Jon, Ph.D. Asst. Prof., Dept. of History, New Mexico State University.

Hunt, George L., Jr., Ph.D. Prof. of Ecology and Evolutionary Biology, Univ. of California, Irvine.

Hunt, Lester H., Ph.D. Assoc. Prof. of Philnsophy, Univ. of Wisconsin, Madison.

Hunt, Melody J., Ph.D. Asst. Prof. of Environmental Engineering, San Diego State Univ.

Hunt, William R., Ph.D, J.D. Author, *Arctic Passage* and *To Stand at the Pole*.

Hunter, Albert, Ph.D. Prof. nf Sociology, Northwestern Univ.

Hunter, O. Frank, M.S. Assoc. Prof., Clemson Univ. School of Textiles, Fiber and Polymer Science.

Hunter, Rob Coauthor, *The Book of Knots*.

Hunter, William D. G. Emeritus Prof. of Economics, McMaster Univ.

Hurd, Bradley, B.A. Former Editor, *The* (Missoula, MT) *Missoulian*.

Hurley, Francis T., D.D. Archbishop of Anchorage.

Hurst, Michael Fellow in Modern History and Politics, St. John's College, Oxford Univ.

Hurt, R. Douglas, Ph.D. Director, Graduate Program in Agricultural History and Rural Studies, Iowa State Univ.

Hurtado, W. Jean, M.A. Editor, HarperCollins Poblishers.

Huse, Nancy Lyman, Ph.D. Prnf. of English, Aogustana Cnllege.

Huseboe, Arthur R., D.H.L. Executive Dir., The Center fnr Western Stodies, Augostana College.

Hustrulid, William, Ph.D. Head, Mining Research and Development, LKAB, Kiruna, Sweden.

Hutchison, Jane Campbell, Ph.D. Prof. of Art History, Univ. of Wisconsin, Madison.

Hutjens, Michael F., Ph.D. Prof. of Animal Sciences and Extension Dairy Specialist, Univ. of Illinois, Urbana-Champaign.

Hutson, James H., Ph.D. Chief, Manoscript Division, Library of Cnngress.

Hyland, Douglas K. S., Ph.D. Directnr, San Antonio Museom of Art.

I

Ibbotson, Roger G., Ph.D. Prof. in the Practice of Finance, Yale School of Management.

Ifkovic, John W., Ph.D. Prof. of History, Westfield State College.

Ihde, Don, Ph.D. Prof. of Philosophy, State Univ. of New York, Stony Brook.

Ihler, Garret M., M.D. Prof. of Medical Biochemistry and Medical Genetics, Texas A&M College of Medicine.

Ilyin, Mary Alexander, B.S.M.E. Mechanical Engineer, Pacific Gas and Electric Co.

Imbelli, Robert P., Ph.D. Assoc. Prof. of Theology, Boston College.

Ingalls, Robert P., Ph.D. Prof. of History, Univ. of South Florida.

Ingersoll, Andrew P., Ph.D. Prof. of Planetary Science, California Institute of Technology.

Ingham, John N., Ph.D. Prof. of History, Univ. of Toronto.

Inglesby, Thomas V., M.D. Asst. Prof., Medicine, Johns Hopkins Univ. School of Medicine.

Ingrao, Charles W., Ph.D. Prof. of History, Purdue Univ.

Ingwersen, Niels, Cand. Mag. Prof. of Scandinavian Studies, Univ. of Wisconsin, Madison.

Insler, Stanley, Ph.D. Salisbury Prof. of Sanskrit and Comparative Philology, Yale Univ.

Ireland, Patrick, Ph.D. Assoc. Prof., Graduate School of International Studies, Univ. of Denver.

Irish, Jerry A., Ph.D. Prof. of Religious Studies, Pomona College.

Irland, Lloyd C., Ph.D. President, The Irland Group; former Budworm Program Coordinator, Maine Forest Service.

Irmscher, William F., Ph.D. Prof. Emeritus of English, Univ. of Washington.

Isenberg, Gerald I., M.B.A. Prof. and Executive Director of Electronic Media Projects, School of Cinema-Television, Univ. of Soothern California.

Isquith, Irwin Richard, Ph.D. Prof. of Biology and Assoc. Dean, Fairleigh Dickinson Univ.

Israel, Paul B., Ph.D. Managing Editor, *Thomas A. Edison Papers*, Rutgers, the State Univ. of New Jersey.

Ito, Philip J., Ph.D. Prof. of Horticulture and Consultant on Tropical Fruits and Nuts, Univ. of Hawaii.

Ivers, Gregg, Ph.D. Prof. and Chair, Dept. of Government, American Univ.

Ivinski, Pamela A., M.A. Art Historian, Graduate Center, City Univ. of New York.

Iwamoto, Tomio, Ph.D. Curator of Ichthyology, California Academy of Sciences.

Iyer, Raghavan, D.Phil. Former Prof. of Political Science, Univ. of California, Santa Barbara.

J

Jackson, Dennis R., M.A. Professional climbing guide and outdoor educatnr.

Thiel, Elizabeth, B.A. Day Metro Editor, *The* (Norfolk, VA) *Virginian-Pilot.*

Thomas, Steve, B.A. Economy Editor, *Savannah* (GA) *Morning News.*

Thomas, Wm. Wayt, Ph.D. Assoc. Curator, New York Botanical Garden.

Thomasma, David C., Ph.D. Former Prof. and Director, Medical Humanities Program, Loyola Univ. Chicago Medical Center.

Thome, G. D., Ph.D. Consulting scientist, Raytheon Co.

Thompson, Brian J., Ph.D. Distinguished Univ. Prof., and Prof. of Optics, Univ. of Rochester.

Thompson, Brian S., Ph.D. Prof. of Mechanical Engineering, Michigan State Univ.

Thumpson, Carol L., M.A. Former Editor, *Current History* magazine.

Thompson, David W., Ph.D. Chancellor Prof. of Chemistry, College of William and Mary.

Thompson, Dennis L., Ph.D. Prof. of Political Science, Brigham Young Univ.

Thompson, Hugh A., M.S. Engineer/Inventor, Procter & Gamble Co.

Thompson, James E., Ph.D. Prof., Chair, Dept. of Electric Engineering, Univ. of Texas, Arlington.

Thompson, John R., Jr., Ph.D. Former Head Basketball Coach, Georgetown Univ.

Thompson, Larry C., Ph.D. Prof. of Chemistry, Univ. of Minnesota, Duluth.

Thompson, Levi T., Ph.D. Prof., Dept. of Chemical Engineering, Univ. of Michigan, Ann Arbor.

Thompson, Louis S., M.B.A. Railways Adviser, World Bank.

Thompson, W. Scott, D.Phil. Adjunct Prof., Georgetown Univ. and Fletcher School of Law and Diplomacy, Tufts Univ.; editor, *The Third World.*

Thompson, Wayne, Ph.D. Historian, Center for Air Force History, Headquarters, U.S. Air Force.

Thomson, Dale C., Ph.D. Prof. of Political Science, McGill Univ.

Thomson, Keith Stewart, Ph.D. President, Academy of Natural Sciences.

Thornton, John I., D.Crim. Emeritus Prof. of Forensic Science, Univ. of California, Berkeley.

Thornton, Lee, Ph.D. Prof. and Chair, College of Journalism, Univ. of Maryland, College Park.

Thurman, Harold V., M.A. Former Prof. of Earth Science, Mount San Antonio College.

Thursby, Gene R., Ph.D. Assoc. Prof. of Religion, Univ. of Florida.

Tidwell, William D., Ph.D. Prof. of Botany, Brigham Young Univ.

Tierney, Kevin, LL.M. Prof. of Law, Hastings College of the Law, Univ. of California, San Francisco.

Tiffney, Bruce H., Ph.D. Assoc. Prof. of Geological Sciences, Univ. of California, Santa Barbara.

Tignor, Robert L., Ph.D. Prof. of History, Princeton Univ.

Tillman, Barrett, B.S. Secretary, American Fighter Aces Association.

Timm, Robert M., Ph.D. Curator of Mammals and Assoc. Prof. of Ecology and Evolutionary Biology, Museum of Natoral History, Univ. of Kansas.

Timms, Howard, B.A. Editorial and Media Director, *World Book Online.*

Tirro, Frank, Ph.D. Prof. of Music, Yale Univ.

Tismaneanu, Vladimir, Ph.D. Prof. of Government and Politics, Univ. of Maryland; Senior Fellow, Foreign Policy Research Institute.

Titman, Rodger D., Ph.D. Assoc. Prof. of Wildlife Biology, Macdonald Campus of McGill Univ.

Tobach, Ethel, Ph.D. Curator Emerita, American Museum of Natoral History, Adjunct Prof. of Biology and Psychulogy, City Univ. of New York.

Todd, James K., M.D. Prof. of Pediatrics, Microbinlogy and Preventive Medicine, Univ. of Colorado School of Medicine.

Todd, Malcolm, D.Litt. Prof. of Archaeology, Univ. of Exeter.

Tong, Phillip S., Ph.D. Prof., Dairy Products Technology Center, California Polytechnic State Univ.

Tonomura, Hitomi, Ph.D. Assoc. Prof. of History; Director, Center for Japanese Studies, Univ. of Michigan.

Tonos, Michael, B.A. Executive Editor, *The* (Biloxi, MS) *Sun Herald*

Toppin, Edgar Allan, Ph.D. Dean of the Graduate School and Prof. of History, Virginia State Univ.

Torrey, E. Fuller, M.D. Research Psychiatrist, National Institute of Mental Health.

Tortike, W. Simon, Ph.D. Assoc. Prof. of Petroleum Engineering, Univ. of Alberta.

Tortora, Phyllis, Ph.D. Prof. Emerita, Home Economics, Queens College, City Univ. of New York.

Towell, W. Patrick, Ph.D. Senior Writer, *Congressional Quarterly.*

Trachtenberg, Marc, Ph.D. Prof. of History, Univ. of Pennsylvania.

Trachtenberg, Marvin, Ph.D. Edith Kitzmiller Prof., Institute of Fine Arts, New York Univ.

Travisono, Anthony P., B.A. Former Executive Director, American Correctional Association.

Trede, Larry D., Ph.D. Prof., Dept. of Agricultural Education and Studies, Iowa State Univ.

Trefil, James, Ph.D. Clarence J. Robinson Prof. of Physics, George Mason Univ.

Tripathi, Brenda, Ph.D. Prof. of Pathology and Adjunct Prof. of Ophthalmology, Univ. of South Carolina School of Medicine.

Tripathi, Ramesh C., F.R.C.Path. Prof. and Chairman, Dept. of Ophthalmology, Univ. of South Carolina School of Medicine.

Tripathi, Vijai K., Ph.D. Prof. of Electrical and Computer Engineering, Oregon State Univ.

Trotta, Paul D., Ph.D. Assoc. Prof. of Engineering, Northern Arizona Univ.

Trotter, William R., B.A. Free-lance writer; author, *A Frozen Hell: The Russo-Finnish Winter War of 1939-1940.*

Troxell, Harry E., D.F. Former Prof. of Forest and Wood Science, Colorado State Univ.

Troy, Nancy J., Ph.D. Chair, Art History Dept., College of Letters, Arts, and Sciences, Univ. of Southern California, Los Angeles.

Truemper, David G., S.T.D. Prof. of Theology, Valparaiso Univ.

Trujillo, Chadwick A., Ph.D. Postdoctoral Scholar in Planetary Science, California Institute of Technology.

Trussell, James, Ph.D. Prof. of Economics and Public Affairs and Director, Office of Population Research, Princeton Univ.

Truzzi, Marcello, Ph.D. Prof. of Sociology, Eastern Michigan Univ.

Tu, Anthony T., Ph.D. Prof. of Biochemistry and Molecular Biology, Colorado State Univ.

Tuck, James A., Ph.D. Prof. of Archaeology, Memorial Univ. of Newfoundland.

Tucker, Barbara M., Ph.D. Prof. of History and Director, Center for Connecticut Studies, Eastern Connecticut State Univ.

Tunks, Thomas W., Ph.D. Assoc. Provost, Southern Methodist Univ.

Tunnell, Ted, Ph.D. Assoc. Prof. of History, Virginia Commonwealth Univ.

Turley, William S., Ph.D. Prof., Dept. of Political Science, Southern Illinois Univ., Carbondale.

Turner, Howard, Ph.D. Prof. of Surveying Engineering, California State Polytechnic Univ., Pomona.

Turner, R. Carroll, M.B.A. Technical Assoc., Carpet and Rug Institote.

Turner, Robert L., M.P.A. Deputy Editor, Editorial page, *Boston Globe.*

Turner, Walter W. Vice President and Manager, Marketing and Development, Industrial Pitch, Koppers Industries, Inc.

Turque, Bill, B.A. Washington Correspondent, *Newsweek*; author, *Inventing Al Gore.*

Tweton, D. Jerome, Ph.D. Former Chester Fritz Distinguished Prof., History, Univ. of North Dakota.

Tyler, Seth, Ph.D. Prof., Dept. of Biological Sciences, Univ. of Maine, Orono.

U

Ubelaker, Douglas H., Ph.D. Curator of Physical Anthropology, Smithsonian Institution.

Uchendu, Victor Chikezie, Ph.D. Director,

Institute of Public Policy, Univ. of Calabar, Nigeria.
Udelson, Joseph H., Ph.D. Prof. of History, Tennessee State Univ.
Uhler, Sharron G., B.Phil. Archivist, Colorado Springs Pioneers Museum.
Ullrich, Arthur H., Jr. Fellow, Academy of Underwater Arts and Sciences; Member, Board of Advisers, National Association of Underwater Instructors.
Ultee, Maarten, Ph.D. Prof. of History, Univ. of Alabama.
Uman, Martin A., Ph.D. Prof. of Electrical and Computer Engineering, Univ. of Florida.
Underwood, T. Bryan, Jr., J.D. Attorney, Northern Trust Co.
Ungar, Sanford J., M.S. Director, Voice of America.
Unger, Richard W., Ph.D. Prof. of History, Univ. of British Columbia.
Urban, Joan Barth, Ph.D. Ordinary Prof. of Politics, Catholic Univ. of America.
Urla, Jacqueline, Ph.D. Assoc. Prof. of Anthropology, Univ. of Massachusetts, Amherst.
Usselman, Melvyn C., Ph.D. Assoc. Prnf. nf Chemistry, Univ. of Western Ontario.
Utley, Robert M., M.A. Former Chief Historian and Asst. Director, National Park Service.

V

Vachon, André, Docteur en Histoire. Fellow of the Royal Society of Canada, historian, and writer.
Vahala, George, Ph.D. Assoc. Prof. of Physics, William and Mary College.
Vail, Leroy, Ph.D. Former Prof. of History, Harvard Univ.
Valbuena, Jose A. Fernandez, Ph.D. Lecturer in Anthropology, Baylor Univ.
Valgemae, Mardi, Ph.D. Prof. of English, City Univ. of New York Herbert H. Lehman College.
Van Camp, Leonard W., D.M.A. Dir. of Choral Activities, Southern Illinois Univ., Edwardsville.
Vance, Charles C. Former Director of Public Relations, National Safety Council.
Vancko, Robert M., Ph.D. Prof. of Mathematics, Ohio Univ.
Van den Berghe, Pierre L., Ph.D. Prof. of Sociology, Univ. of Washington.
Vandergrift, Kay E., Ed.D. Assoc. Dean, School of Communication, Information and Library Stodies, Rutgers, the State Univ. of New Jersey.
Van der Linden, F. Robert, M.A. Corator of Aeronaotics, National Air and Space Museom.
VanDerWege, David, M.S. Director of Member and Field Services, American Camping Assoc.
Vander Zanden, James W., Ph.D. Former Prof. of Sociology, Ohio State Univ.
Vandiver, Frank, Ph.D. Author, *Rebel Brass: The Confederate Command System.*
Vandiver, J. Kim, Ph.D. Dean for Undergradoate Research, Massachosetts Institote of Technology.
Van Dusen, Albert E., Ph.D. Emeritus Prof. of History, Univ. of Connecticot.
Van Riper, Charles, III, Ph.D. Prof. of Biology, U.S. Geological Survey, Northern Arizona Univ.
Van Riper, Sandra, M.S. Science writer.
Van Tine, Warren, Ph.D. Prnf. of History, Ohio State Univ.
VanWingen, Peter M., M.S. in L.S. Former Specialist for the Book Arts, Library of Cnngress.
Vardy, Steven Bela, Ph.D. Prof. of History, Doqoesne Univ.
Vardys, V. Stanley, Ph.D. Former Prof. nf Political Science, Univ. of Oklahoma.
Vatai, Frank L., Ph.D. Asst. Prof. of History, California State Univ., Northridge.
Vaughan, Alden T., Ph.D. Prof. of History, Columbia Univ.
Vehrencamp, Sandra L., Ph.D. Prof. of Neurobiology and Behavior, Cornell Lab. of Ornithology.
Veillette, Robert D., B.G.S. Managing Editnr, *The Waterbury* (CT) *Republican-American.*
Venit, Marjorie S., Ph.D. Assoc. Prof. of Art History and Archaeology, Univ. of Maryland.
Verderher, Nadine L., Ph.D. Former Prof. of Mathematics, Southern Illinois Univ., Edwardsville.
Vergano, Peter J., Sc.D. Assoc. Prof. of Packaging Science, Clemson Univ.
Verity, John W. Dept. Editor, *Business Week.*
Vermeer, Donald E., Ph.D. Prof. and Chair, Dept. of Geography and Regional Science, George Washington Univ.
Ver Steeg, Clarence L., Ph.D. Prof. of History, Northwestern Univ.
Verts, William T., Ph.D. Asst. Prof., Dept of Computer Science, Univ. of Massachusetts, Amherst.
Vickery, John B., Ph.D. Prof. of English Emeritus, Univ. of California, Riverside.
Videon, Fred F., Ph.D. Senior Structural Engineer, Bridger Engineers, Inc.
Vietor, Richard H. K., Ph.D. Senator John Heinz Prof. of Environmental Management, Harvard Univ. Graduate School of Business Administration.
Vincenti, Virginia B., Ph.D. Prof., Dept. of Family and Consumer Sciences, Univ. of Wyoming.
Vinquist, Mary, Ph.D. Author, *Performance Practice: A Bibliography.*
Vinson, S. Bradleigh, Ph.D. Prof. of Entomology, Texas A&M Univ.
Visich, Marian, Jr., Ph.D. Assoc. Dean of Engineering, State Univ. of New York, Stony Brook.
Vitt, Dale H., Ph.D. Prof., Dept. of Plant Biology, Southern Illinois Univ., Carbondale.
Vitt, Laurie J., Ph.D. Prof. of Biology, Univ. of California, Los Angeles.
Vizenor, Gerald, B.A. Prof., American Studies, Univ. of California, Berkeley.
Vogel, Morris J., Ph.D. Prof. of History, Temple Univ.
Vogele, William B., Ph.D. Asst. Prof. of Political Science and Coordinator of the Program in Social and Political Systems, Pine Manor College.
Voorhies, Michael R., Ph.D. Curator, Vertebrate Paleontology, Univ. of Nebraska State Moseum.
Voyles, J. Bruce, B.A. Publisher and Author, Chattanooga, TN.

W

Wacker, Peter O., Ph.D. Prof. of Geography, Rutgers, the State Univ. of New Jersey.
Waddell, Eileen, M.A. Asst. Managing Editor, *The* (Columbia, SC) *State.*
Wade, John W., S.J.D. Former Dean and Prof. of Law, Vanderbilt Univ. School of Law.
Wade, Thomas Edward, Ph.D. Professor of Electrical Engineering, Univ. of South Florida.
Wadsworth, Frank W., Ph.D. Prof. Emeritus, State Univ. of New York College, Porchase.
Wagner, David H., Ph.D. Senior Scientist, Northwest Botanical Institute.
Wagner, John E., Jr., M.D. Assoc. Director, Blood and Marrow Transplantation, Univ. of Minnesota, Minneapolis.
Wagner, Mary Emma, Ph.D. Lecturer Emerita in Geology, Univ. of Pennsylvania.
Wagner-Martin, Linda, Ph.D. Hanes Prof. of English, Univ. of North Carolina, Chapel Hill.
Wailes, B., Ph.D. Assoc. Prof. of Anthropology, Univ. of Pennsylvania.
Waiser, Bill, Ph.D. Head, Dept. of History, Univ. of Saskatchewan.

Aa

A is the first letter of our alphabet. It was the first letter in all the alphabets from which ours evolved. The Semites, who lived in Syria and Palestine, named their first letter *aleph,* meaning *ox.* They adapted an Egyptian *hieroglyphic* (picture symbol) for an ox. The ancient Greeks later used this symbol, and called it *alpha.* Our word *alphabet* comes from *alpha* and *beta,* the second letter in Greek. The Romans gave the letter its present form. See **Alphabet.**

Uses. *A* or *a* is about the third most frequently used letter in books, newspapers, and other printed material in English. When used on a report card, *A* represents the highest grade given in a school subject. In Latin, *a* stands for *ante,* or *before,* as in *a.m.* for *ante meridiem,* or *before noon.* The *a* is used to abbreviate such words as *adjective, alto,* and *ampere.*

Pronunciation. In English, the principal sound of *A* or *a* is long *a,* as in *fate.* Long *a* is pronounced by raising the tongue toward the roof of the mouth and holding the mouth slightly open. Short *a,* as in *hat,* is pronounced with the tip of the tongue below the edges of the lower front teeth, the back of the tongue raised, the jaw lowered, and the lips moderately open. Broad *a,* as in *father,* is pronounced with the tip of the tongue placed first below the edges of the lower front teeth and later raised. The mouth is opened wide. Unstressed *a,* as in *loyal* or *about,* is roughly equivalent to unstressed *u* in *unfit.* See **Pronunciation.** Marianne Cooley

Development of the letter A

The ancient Egyptians, about 3000 B.C., drew this symbol of an ox's head.

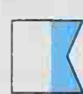
The Semites simplified the Egyptian symbol about 1500 B.C. They called their letter *aleph,* their word for *ox.*

The Phoenicians, about 1000 B.C., simplified the Semitic letter.

The Greeks adapted the letter about 600 B.C. They called it *alpha* and made it the first letter of their alphabet.

The Romans gave the letter A its present form about A.D. 114.

The small letter a appeared during the A.D. 300's. It had developed its present shape by about 1500.



A.D. 300 — 1500 — Today

Common forms of the letter A

Aa *Aa*

Handwritten letters vary from person to person. *Manuscript* (printed) letters, *left,* have simple curves and straight lines. Cursive letters, *right,* have flowing lines.

Aa *Aa*

Roman letters have small finishing strokes called *serifs* that extend from the main strokes. The type face shown above is Baskerville. The italic form appears at the right.

Aa *Aa*

Sans-serif letters are also called *gothic letters.* They have no serifs. The type face shown above is called Futura. The italic form of Futura appears at the right.

A

Computer letters have special shapes. Computers can "read" these letters either optically or by means of the magnetic ink with which the letters may be printed.

Aachen, *AH kuhn* (pop. 238,587), is an industrial city in Germany. It is called Aix-la-Chapelle by the French. For the location of Aachen, see Germany (political map).

A number of historic buildings stand near the center of Aachen. The magnificent cathedral was begun by the European ruler Charlemagne during the 700's and contains his tomb. The Imperial and City Hall dates from 1330 and is a fine example of Gothic architecture. It houses a number of art treasures. Each year, thousands of people visit the city's resort, Bad Aachen (pronounced *BAHD AH kuhn),* whose hot mineral springs are believed to cure some ailments. Aachen's factories produce machinery, metal products, and textiles.

Roman soldiers established a settlement on the site of Aachen shortly after the birth of Jesus Christ. Charlemagne was born in Aachen in 742 and made it the capital of his western European empire. Peter H. Merkl

Aalto, *AHL taw,* **Alvar,** *AHL vahr* (1898-1976), was a Finnish architect, town planner, and furniture designer. He gained fame for buildings that imaginatively combine modern design principles with traditional materials, especially wood. Aalto often used flowing, wavy forms that marked a strong departure from the strict geometric lines favored by other modern architects.

Aalto designed his first two major works in the 1920's, a tuberculosis sanitarium in Paimio, Finland, near Turku, and a municipal library in Viipuri, Finland (now Vyborg, in Russia). He designed birchwood tables and chairs for these projects that made him famous as a furniture designer. His other buildings include a number of civic, university, and apartment buildings. The Hall of Residence (1947-1949), at the Massachusetts Institute of Technology, with its curved facade, is one of his most distinguished buildings in North America. The Aalto Theater, an opera house he designed in Essen, Germany, opened in 1988, after his death. Aalto's projects as a town planner include a town center in Seinäjoki, Finland. The center features several small wedge-shaped buildings, largely made of wood. Aalto was born on Feb. 3, 1898, in Kuortane, near Vaasa. Nicholas Adams

Aardvark, *AHRD vahrk,* is an African mammal that eats ants and termites. It has an arched body with a tubelike snout, large ears, and a long tail. The animal hunts for food at night and sleeps in a burrow during the day. In the 1600's, Dutch settlers in southern Africa gave the aardvark its name, which means *earth pig.*

Aardvarks grow 4 to 6 feet (1.2 to 1.8 meters) long and weigh about 140 pounds (64 kilograms). Their coarse hair ranges from pinkish to grayish. The animals lack front teeth. But peglike molars on the sides of their mouths grow continuously. Unlike teeth of many mammals, aardvarks' molars have no enamel coating. Instead, a hard tissue called *cementum* covers the teeth. Aardvarks have four sharp, spoon-shaped claws on their front feet and five on their hind feet. When attacked, they roll on their backs and use their claws for defense. Lions, leopards, and people often kill aardvarks for food.

An aardvark digs burrows faster than most other animals. It can make a deep hole in only a few minutes. Permanent burrows may extend to 43 feet (13 meters) in length. The aardvark does not have good eyesight, but it uses its excellent senses of smell and hearing to find prey. When an aardvark searches for food, its snout stays close to the ground and its ears point forward. The animal uses its claws to rip open ant or termite nests, and it licks up the insects with its long, sticky tongue. The tongue is about 12 inches (30 centimeters) long.

Norman Myers, Bruce Coleman Ltd.

The aardvark rips open the nests of ants and termites with its claws. Then it catches the insects with its long, sticky tongue.

Females give birth to one baby at the start of the rainy season. Young aardvarks start digging burrows at about 6 months of age. After about a year, males move away from their mothers. Young females also become independent but stay near their mothers. Duane A. Schlitter

Scientific classification. The aardvark is the only living member of the order Tubulidentata. It is *Orycteropus afer.*

Aardwolf, *AHRD wulf,* is an unusual type of hyena that lives on the plains of southern and eastern Africa. Most hyenas have powerful jaws and strong teeth, but the aardwolf's teeth are small, weak, and cone-shaped. It feeds chiefly on termites, which it laps up with its broad, sticky tongue. The aardwolf is unlike other hyenas because it has five toes on its front feet, and four toes on its hind feet. Other kinds of hyenas have four toes on each foot. It is also smaller than other hyenas, standing 20 inches (51 centimeters) high at the shoulder.

Aardwolves live alone, in pairs, or in family groups with two to four young. The aardwolf has a mane along

© Tom McHugh, Photo Researchers

The aardwolf is tawny-colored with black stripes, black feet, and a black-tipped bushy tail. It is not a wolf but a hyena.

the back. It can raise the mane to make itself look larger.

The name *aardwolf,* which is Afrikaans for *earth wolf,* was given the animal because it lives in a burrow. Aardwolves only come out at night. Anne Innis Dagg

Scientific classification. Aardwolves are in the hyena family, Hyaenidae. They are *Proteles cristatus.*

Aaron, *AIR uhn,* in the Bible, was the brother of Moses and Miriam. In earlier Biblical traditions, he was seen as a prophet and as Moses's helper. In later traditions, he was viewed as the first high priest of Israel. Aaron may have originally played an independent role from Moses in the Israelites' deliverance from slavery in Egypt. Like Moses, Aaron was denied entrance into Canaan and died on Mount Hor in Edom. The priestly traditions in the Bible give Aaron an expanded role in Israelite religious life and consider him founder of the Aaronite priesthood. This priesthood became important in Jerusalem after the Israelite return from exile in 538 B.C. See also **Moses; High priest; Birthstone.** Carole R. Fontaine

Aaron, *AIR uhn,* **Henry** (1934-), hit 755 regular-season home runs, more than any other baseball player in major league history. Aaron hit his 715th home run, which broke Babe Ruth's record of 714 homers, on April 8, 1974.

Aaron played for the Milwaukee (later Atlanta) Braves of the National League from 1954 through 1974. He was traded to the Milwaukee Brewers of the American League following the 1974 season and retired as a player after the 1976 season. Aaron played right field most of his career but also played left field, center field, and first base.

Atlanta Braves

Henry Aaron

Aaron led the National League in home runs in 1957, 1963, 1966, and 1967. He won the league batting championship twice. He also holds the major league career record for runs batted in—2,297. Aaron led the National League in runs batted in four times. He received the 1975 Spingarn Medal, and he was elected to the National Baseball Hall of Fame in 1982. Henry Louis Aaron was born on Feb. 5, 1934, in Mobile, Alabama. Dave Nightingale

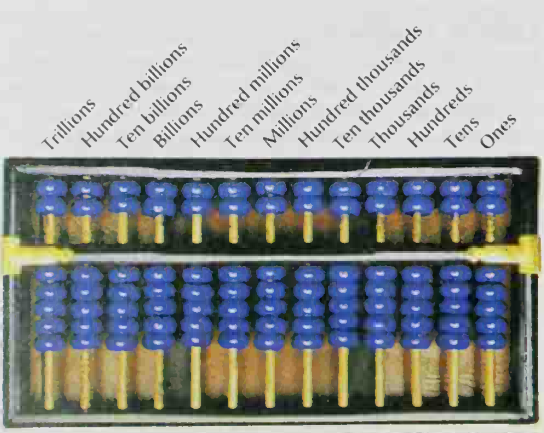
AARP, *ahrp,* is the largest private nonprofit membership organization in the world. Its name is a shortened form of its original title, the American Association of Retired Persons. It has over 30 million members, who must be 50 years old or older.

AARP's main purpose is to address the needs of older people in the United States. It does this by providing them with education and services and by representing their interests before government agencies and other public bodies. AARP also works to improve the lives of older people by promoting their independence and dignity and by encouraging them to pursue personal goals. AARP offers members a number of benefits, including group health insurance, legal services, and a mail-order pharmacy. The AARP magazine, *Modern Maturity,* is the largest circulation magazine in the United States.

Ethel Percy Andrus, a retired educator, founded the American Association of Retired Persons in 1958. The group changed its name to AARP in 1998. Its headquarters are in Washington, D.C. For more information, see its Web site at www.aarp.org. Critically reviewed by AARP

AAUW. See **American Association of University Women.**



Abacá, *AH buh KAH,* is a plant grown in Borneo, the Philippines, and Sumatra for its fiber. The plant grows about 20 feet (6 meters) high and has large oblong leaves. The leaves grow from the trunk of the plant, and the bases of the leaves form a *sheath* (covering) around the trunk. These sheaths contain the valuable fiber. The coarse fibers grow 5 to 11 $\frac{1}{2}$ feet (1.5 to 3.5 meters) long and consist primarily of the plant materials cellulose, lignin, and pectin. Abacá fiber is sold under the name *manila,* after the major city of the Philippines. See also **Philippines** (picture: Manila hemp). Christine W. Jarvis

Scientific classification. The abacá plant belongs to the banana family, Musaceae. It is *Musa textilis.*

Abacus, *AB uh kuhs,* is an ancient device used in China and other countries to perform arithmetic problems. It can be used to add, subtract, multiply, and divide, and to calculate square roots and cube roots. The abacus consists of a frame containing columns of beads. The beads, which represent numbers, are strung on wires or narrow wooden rods attached to the frame.

The abacus was used by the ancient Greeks and Romans. The Chinese abacus is called *suanpan,* which means *counting,* or *reckoning, board.* A typical Chinese abacus has columns of beads separated by a crossbar. Each column has two beads above the crossbar and five below it. Each upper bead represents five units, and each lower bead equals one unit.

The first column on the right is the ones column. The second column is the tens column. The third column is the hundreds, and so on. The ones column represents numbers from one to nine. Each bead below the cross

WORLD BOOK photo by Dan Miller

bar has a value of one (or 1), and each bead above the crossbar has a value of 5 ones (or 5). The tens column represents numbers from 10 to 90. Each lower bead in the tens column represents 1 ten (or 10), and each upper bead represents 5 tens (or 50). A number is represented on the abacus by moving the appropriate beads to the crossbar. Arthur Gittleman

Abadan, *AH bah DAHN,* (pop. 206,073), is a refining center for Iran's oil industry. It lies on Abadan Island, on the Shatt al Arab River in southwestern Iran (see Iran [map]). Pipelines link Abadan with Iranian oil fields. The city's petroleum refinery, completed in 1913, ranks among the largest in the world. It was badly damaged by Iraqi forces in 1980, during a war between Iran and Iraq. The Anglo-Persian Oil Company, a British firm, began the development of Abadan in the early 1900's. Michel Le Gall

Abalone, *AB uh LOH nee,* is a marine snail found in most mild and tropical seas. It is sometimes called an *ear shell* or *ormer.* It is found along the coasts of California, Australia, Japan, New Zealand, South Africa, and Europe. It clings to submerged rocks by means of a flat, muscular foot. It feeds on plants that it scrapes off the rocks with its filelike tongue. Abalone steak, the snail's muscular foot, is a popular seafood dish on the Pacific Coast of the United States and in Japan. The abalone's colorful shell, which may be from 1 to 12 inches (2.5 to 30 centimeters) long, is used in making costume jewelry. See also Mother-of-pearl. Robert Robertson

Scientific classification. Abalones are in the family Haliotidae, and the genus *Haliotis.*

Abandonment is a legal term that has two chief meanings. In the field of property law, abandonment occurs when a person intentionally gives up all rights to something he or she owns. For example, if a person purposely throws away a ring, it has been abandoned. In family law, abandonment refers to the desertion of a husband, wife, or child without intention to support the person. Most states of the United States make it a crime for a parent to abandon a child. A father or mother who does this may lose the right to raise the child.

Abandonment, also called *desertion,* is grounds for divorce in states that permit divorce because of a wrong done by the husband or wife (see Desertion). Some states allow *no-fault divorce,* in which one of the partners simply testifies that the marriage has failed. As a result of no-fault divorce, fewer people seek divorce on the ground of abandonment. Mary Ann Glendon

Abbado, Claudio (1933-), is an internationally known Italian symphony orchestra and opera conductor. Abbado has been music director of several of the major orchestras and opera companies in Europe.

Abbado was born on June 26, 1933, in Milan, Italy. He studied piano with his father, and at the Milan Conservatory. He then studied conducting at the Vienna Academy of Music. Abbado won two prestigious international conducting competitions in 1958 and 1963. By the mid-1960's, he had become recognized as one of the leading conductors of his generation.

In 1968, Abbado became principal conductor of the La Scala opera in Milan. He served as the institution's music director from 1971 to 1986. He won praise for raising the artistic standards of the La Scala orchestra both in opera and in concert performances. Abbado was principal conductor for the London Symphony Orchestra from 1979 to 1988. He was also music director for the Vienna State Opera from 1986 to 1991.

Abbado became principal conductor for the Vienna Philharmonic in 1971 and artistic director and principal conductor of the Berlin Philharmonic Orchestra in 1989. Over the years, Abbado has established several new orchestras and music festivals. He has been especially interested in training young musicians. John H. Baron

Abbas I, *ab BAHS* (1571-1629), was the *shah* (king) of the Safavid dynasty in Southwest Asia from 1587 until his death in 1629. Under Abbas, the Safavids reached the height of their power, ruling all or parts of present-day Iran, Iraq, Azerbaijan, Turkmenistan, and Afghanistan.

Abbas brought peace and stability to an empire that had been weakened by internal conflict since the 1570's. Before Abbas's reign, the Safavids relied on Turkic warriors called Qizilbash (Red Heads) for military and administrative support. But Qizilbash tribes constantly fought with one another for power. As shah, Abbas reduced Qizilbash influence by creating an army of Georgian, Armenian, and Circassian slaves who were loyal only to him. He also seized land that had been under Qizilbash control. Under Abbas, the Safavids regained territory that had been lost to the Ottoman Empire in the west and to the Uzbek and Mughal empires in the east.

Abbas relocated the Safavid capital to the Persian city of Isfahan in 1598. He turned Isfahan into a splendid capital with a magnificent public square and beautiful mosques, palaces, and gardens.

Abbas was born on Jan. 27, 1571, in Herat, a city in what is now Afghanistan. He died on Jan. 19, 1629, in Ashraf (now Behshahr). Kathryn Babayan

See also Isfahan; Safavid dynasty.

Abbot is the religious superior of a monastery of an early religious order, such as the Benedictines and Cistercians. The term comes from the Aramaic word *abba,* which means *father.* Young Egyptian monks first used the title in the early 300's. These monks would seek an older monk or a hermit of the desert, whom they called *abba,* to teach and guide them. In the 500's, the Benedictine order established the title for the monk who had authority over other monks and monastic property.

In early times, monks often appointed an abbot for life. In the Middle Ages, abbots were often appointed by civil officials. Today, monks elect an abbot, usually to serve a limited term. Abbots are generally independent of the local bishop. A woman who is the head of an abbey of nuns is called an *abbess.* David G. Schultenover

Abbott was the name of two sisters who were American social-work pioneers. They were born in Grand Island, Nebraska—Edith on Sept. 26, 1876, and Grace on Nov. 17, 1878.

Edith Abbott (1876-1957) taught at the Chicago School of Civics and Philanthropy and was dean of the University of Chicago's School of Social Service Administration from 1924 to 1942. She fought against injustices in the treatment of the poor and was a critic of politics in welfare programs. She helped awaken the government to its responsibility in the welfare field.

Grace Abbott (1878-1939) was chief of the United States Children's Bureau from 1921 to 1934 and fought for the rights of women and children worldwide. She was on the Committee on Economic Security, which developed the Social Security Act. Alan Keith-Lucas

Sir John Joseph Caldwell Abbott

Prime Minister of Canada
1891-1892

Macdonald
1878-1891

Abbott
1891-1892

Thompson
1892-1894

The Public Archives of Canada, Ottawa

Abbott, Sir John Joseph Caldwell (1821-1893), served as prime minister of Canada from June 1891 to November 1892. He succeeded Sir John A. Macdonald, who died in office. During his administration, Abbott faced many problems that he could not solve. They included a severe nationwide depression and major conflicts between English- and French-speaking Canadians. Abbott became prime minister at the age of 70 and resigned because of poor health.

Abbott was a distinguished lawyer, a position that drew him into politics. Before becoming prime minister, he had served in the Assembly of the Province of Canada and in the Canadian Parliament. He also had been dean of the law school of McGill College (now McGill University) in Montreal.

Abbott claimed he did not like politics. He said he held political office because he believed public service was his duty. Shortly before taking office as prime minister, Abbott wrote a friend, "I hate notoriety, public meetings, public speeches, caucuses, and everything that I know of what is apparently the necessary incident of politics—except doing public work to the best of my ability."

Abbott had a wide range of interests. He owned a salmon stream where he often fished, and he grew many varieties of rare orchids. He also loved animals and helped establish the Canadian Society for the Prevention of Cruelty to Animals.

Early life. John Abbott was born on March 12, 1821, in St. Andrews, near Montreal, Lower Canada (present-day Quebec province). His father, Joseph Abbott, was an Anglican missionary who had come there from England in 1818. Soon after arriving in Canada, he married Harriet Bradford, the daughter of a Canadian minister.

The Abbott family moved to Grenville, Lower Canada, in 1830, but John spent much time with an uncle in St. Andrews. He learned about astronomy and mathematics from a retired sea captain there and attended school in the nearby village of Carillon.

Abbott left home at age 17 and began a business career, which he followed most of the time through the mid-1840's. He conducted his activities, which included selling cloth, packing apples, and buying grain, in Montreal and other communities. He interrupted these activities to attend law school at McGill College.

Abbott received a law degree in 1847 and began to practice in Montreal that year. He specialized in corporation law and soon became known as an authority in this field. In 1849, he married Mary Bethune, whose father was the principal of McGill College. Abbott served as dean of the law school at McGill from 1855 to 1880.

Early political career. Abbott was elected to the legislature of the Province of Canada in 1857 and served until 1867. He entered politics as a Liberal but gradually shifted toward the Conservative Party. During the early 1860's, some Conservatives favored the unification under one government of all the British colonies in North America. In 1865, Abbott joined these Conservatives in support of the movement for confederation. The Dominion of Canada was established in 1867. It consisted of the provinces of New Brunswick, Nova Scotia, Ontario, and Quebec. That same year, Abbott was elected to the Dominion's first House of Commons, where he served until 1874.

Abbott continued his thriving law practice while serving as a legislator. During the early 1870's, he became involved in negotiations for the construction of a Canadian transcontinental railroad. Two financial groups were competing for the construction contract. One group was headed by a client of Abbott's, Sir Hugh Allan, a Montreal shipping line owner. Abbott tried to unite the two groups into one company, but he could not do so. Allan's group eventually received the construction contract.

The Pacific Scandal. In 1873, a clerk in Abbott's office stole some papers that revealed large campaign contributions by Allan to the Conservatives in the 1872 general election. The papers included a telegram in which Prime Minister John A. Macdonald, the Conservative leader, had demanded of Allan: "Send me another ten thousand. Do not fail me." Liberal members of Parliament acquired the papers and revealed their contents. Macdonald admitted receiving the money, but he denied that the contributions had influenced his decision to give the contract to Allan. The government appointed a royal commission to investigate the case, which became known as the Pacific Scandal.

The scandal finally forced Macdonald to resign as prime minister in November 1873 and led to formation of a Liberal government headed by Alexander Mackenzie. Abbott lost his seat in the House in the 1874 election. Historians disagree about Abbott's involvement in the scandal. Most believe he was innocent of personal misconduct but was probably aware of some of the dealings between Macdonald and Allan.

The railroad project was abandoned after the Pacific Scandal, and Mackenzie failed in his efforts to reorganize it. The Conservatives regained control of Parliament in 1878, and Macdonald again became prime minister. He quickly revived the railroad plans. In 1880, Abbott became the lawyer of the Canadian Pacific Railway. He wrote the charter for the railroad, which was completed in 1885.

Return to Parliament. Abbott was reelected to the Canadian House of Commons in 1880 and served until 1887. He was then appointed to Macdonald's Cabinet and to the Canadian Senate, where he served as government leader. In 1887, Abbott was also elected mayor of Montreal, a position he held until 1889. In 1891, Prime Minister Macdonald wanted to increase Abbott's duties in the Cabinet. However, Abbott refused because he did not feel capable of handling more speeches and public meetings.

Prime minister. Macdonald died in June 1891. The Conservatives wanted either Sir John S. D. Thompson, the Minister of Justice, or Sir Charles Tupper, the Canadian High Commissioner in the United Kingdom, to be the party leader. Both Thompson and Tupper refused the position, however, and Abbott was chosen. Abbott, who preferred Thompson for the leadership, reluctantly took over as party leader and became prime minister. Abbott relied on Thompson to handle many of the responsibilities in the House of Commons and in the Cabinet.

Even before Abbott took office, a scandal in the public works department had shaken the Conservative government. Some employees in that department were found guilty of awarding railroad contracts to companies in exchange for money. An investigation was conducted, and the department head, Sir Hector-Louis Langevin, was found to have been negligent. Abbott asked for his resignation, and Langevin submitted it in September 1891.

In 1892, the Manitoba school dispute caused additional problems for Abbott's administration. The Manitoba provincial government had passed a law in 1890 that abolished tax support for Roman Catholic and French-language schools. A single nonreligious school system was established, with English as the official language. The Roman Catholic and French-speaking population in Manitoba charged that this action violated a law of 1870. In 1891, the Supreme Court of Canada had declared the 1890 law unconstitutional. However, in the summer of 1892, the court's ruling was reversed by the British Privy Council, which was then the highest court of appeal. Tension between English- and French-speaking Canadians increased. But Abbott, with Thompson's help, prevented a political crisis by keeping the dispute in court.

A depression that had hit Canada in 1890 became worse during Abbott's term. His health began to fail, and he was able to handle fewer responsibilities. Queen Victoria of Britain knighted Abbott in May 1892. He went to London in October for medical advice but resigned from office in November. Thompson succeeded Abbott as leader of the Conservative Party and as prime minister. Abbott later returned to Montreal, where he died on Oct. 30, 1893. P. B. Waite

Additional resources

Donaldson, Gordon. *The Prime Ministers of Canada.* Doubleday, 1994. Includes a chapter on Abbott.

Waite, P. B. *Canada, 1874-1896: Arduous Destiny.* 1971. Reprint. Oxford, 1996. Examines the years of the Abbott administration.

Abbott, Robert Sengstacke (1868-1940), was an African American journalist. He founded the *Chicago Defender,* which became one of the nation's largest and most influential black newspapers.

Under Abbott's leadership, the *Defender* encouraged Southern blacks to move to the industrial states of the North. Beginning in the 1910's, and continuing after World War I (1914-1918), hundreds of thousands of blacks moved to the North in search of better job opportunities. Abbott's editorials demanded full equality for blacks.

Chicago Daily Defender
Robert Sengstacke Abbott

Abbott was born on Nov. 28, 1868, on St. Simon's Island, Georgia. His parents had been slaves. He learned about printing at his stepfather's newspaper, the *Woodville* (Georgia) *Times,* and later at Hampton Institute in Virginia. Abbott put himself through Kent Law School (now Chicago-Kent College of Law) by working as a printer. He graduated in 1899 and became a lawyer. But he decided he could better serve African Americans by publishing a newspaper. He founded the *Chicago Defender,* a weekly, in 1905.

In 1956, under John H. Sengstacke, Abbott's nephew and successor, the *Defender* became a daily. Around the *Defender,* Sengstacke built the largest chain of black newspapers in the United States. Robert K. Stewart

Abbreviation is a shortened form of a word or a phrase. Some abbreviations include only initial letters of a word, as when *Feb.* stands for *February.* Other abbreviations use first and last letters, as when *VT* stands for *Vermont.* Key letters in a word or phrase may also be used, as when *VCR* stands for *v*ideo*c*assette *r*ecorder.

Abbreviations save space. They are used in tables, in technical and scientific material, and in indexes, footnotes, and bibliographies. They are also used instead of long official names, as in *AFL-CIO* (*A*merican *F*ederation of *L*abor and *C*ongress of *I*ndustrial *O*rganizations). Abbreviations called *acronyms* are words made up of the first letters or syllables of other words, such as UNESCO (United Nations Educational, Scientific and Cultural Organization). Such abbreviations are often written without periods. Symbols that are not made up of letters of the alphabet are not abbreviations, but they serve the same purpose abbreviations do (see Symbol).

Abbreviations have been found on the earliest known tombs, monuments, and coins. When manuscripts were written by hand, abbreviations were used to save time and space. Many Latin abbreviations are still used.

Many *World Book* articles contain abbreviations in lists, tables, picture credits, and captions. Abbreviations are also used to a limited extent in the text of articles. This article includes a table of abbreviations commonly used in published works. Other categories of abbreviations can be found in the following *World Book* articles:

Canadian provinces. Abbreviations are given in the Canada article in the table *The provinces and territories of Canada.*

College degrees. Some common abbreviations can be found in the article **Degree, College.**

New Deal agencies. Abbreviations for many New Deal agencies are in a table in the article **New Deal.**

Proofreading. The most common abbreviations and marks used by proofreaders are in a table in the article **Proofreading.**

States. Abbreviations for the states are in a table with the article **United States.**

United Nations. Abbreviations for United Nations agencies and committees are given in the table *The United Nations system* with the article **United Nations.**

Weights and measures. Abbreviations can be found in tables with the article **Weights and measures.**

WORLD BOOK illustration by Robert Demarest

The abdomen is a large body cavity that lies between the *thorax* (chest) and the pelvic cavity. The abdomen contains various internal organs, including the major organs of digestion.

Abdomen is a large body cavity between the *thorax* (chest) and the pelvic cavity. A strong wall of muscle, called the *diaphragm,* separates the abdomen from the thorax. But no structure separates the abdomen from the pelvic cavity. The abdominal organs include the stomach, liver, pancreas, intestines, kidneys, adrenal glands, and spleen. A thin membrane known as the *peritoneum* lines the entire abdominal cavity and covers most of the abdominal organs. Two large blood vessels, the *aorta* and *vena cava,* run along the spine and pass through the diaphragm and into the thorax.

The front wall of the abdomen consists of layers of sheetlike muscles attached to the ribs above and the pelvic bones below. These muscles hold in the abdominal organs and assist in bending and rotating the body trunk. Other muscles and the backbone form the rear wall of the abdomen.

The abdomen is the part of the body behind the thorax of insects, crustaceans, and certain other kinds of animals without backbones. Laurence H. Beck

Abdul-Jabbar, *AHB dool juh BAHR,* **Kareem,** *kuh REEM* (1947-), became one of the greatest centers in basketball history. Standing 7 feet 2 inches (218 centimeters) tall, he combined his height advantage with quick, graceful movements, fine shooting, and excellent teamwork. He was especially known for a sweeping hook shot that became known as the "sky hook."

Abdul-Jabbar played in the National Basketball Association (NBA) from 1969 until his retirement at the end of the 1988-1989 season. During his professional career, he scored a record 38,387 regular-season points. He played in 1,560 regular season games over 20 seasons. Abdul-Jabbar led the NBA in scoring in the 1970-1971 and 1971-1972 seasons. He was named the league's Most Valuable Player six times.

During his college career, Abdul-Jabbar led UCLA to national championships in 1967, 1968, and 1969. After graduation, he joined the Milwaukee Bucks of the NBA. In 1975, he was traded to the Los Angeles Lakers, finishing his career with that team.

Abdul-Jabbar was born in New York City. His given and family name was Ferdinand Lewis Alcindor, Jr. He received the name Kareem Abdul-Jabbar when he adopted the Islamic religion in 1971. His name was legally changed to Abdul-Jabbar in 1971. An autobiography, *Kareem,* was published in 1990. Bob Logan

Focus on Sports

Kareem Abdul-Jabbar scored more points than any other player in the history of the National Basketball Association.

Abdullah II, *ab DUHL uh* or *ab dool LAH* (1962-), became king of Jordan in 1999, following the death of his father, Hussein. He is the oldest son of Hussein and his second wife, Princess Muna al-Hussein. Before taking the throne, Abdullah was a career military officer.

Abdullah was born in Amman, the capital of Jordan, and attended high school at Deerfield Academy in the United States. In the 1980's, he studied international relations at Oxford University in the United Kingdom and Georgetown University in the United States. He also had military training at schools in both countries.

In 1981, Abdullah joined the Jordanian army as a second lieutenant. He was promoted to colonel in 1993 and became commander of Jordan's special forces in 1994. While in the military, Abdullah represented his father on diplomatic missions to the Middle East, Europe, and the United States.

Abdullah is married to Queen Rania Abdullah, a Palestinian from the West Bank. They have a son, Hussein, and a daughter, Iman. Peter Gubser

À Becket, Thomas. See Becket, Saint Thomas.

Abel, *AY buhl,* the second son of Adam and Eve, was a shepherd (Genesis 4). He offered some of the first born of his flocks as a sacrifice to the Lord. His sacrifice was accepted. But when his older brother, Cain, who was a farmer, offered "fruit of the ground," his sacrifice was refused. Cain grew angry and killed Abel. See also Adam and Eve; Cain. Carole R. Fontaine

Abelard, *AB uh LAHRD,* **Peter** (1079-1142), was one of the leading philosophers and theologians of the Middle Ages. But he is probably best known for his love affair with Héloïse, a gifted young Frenchwoman.

Abelard was born near Nantes, France. His father, a nobleman, planned a military career for him, but Abelard became a scholar. From 1113 to 1118, he taught theology in Paris. There, Abelard founded a school that, along with two others, developed into the University of Paris.

In 1113, Abelard became the tutor of Héloïse, the niece of an official of the Cathedral of Notre Dame. A love affair developed between Abelard and the young woman, and she became pregnant. Soon after the birth of their baby in 1118, Héloïse and Abelard were secretly married. Fulbert, Héloïse's uncle, learned of the love affair and marriage and was outraged. In anger, Fulbert hired several men who broke into Abelard's house and castrated him. After the attack, Abelard and Héloïse separated. Abelard became a monk, and Héloïse joined an order of nuns. The fame of their tragic love affair resulted largely from the many letters they exchanged.

Abelard's major contributions to medieval thought were in the areas of logic and theology. He urged the use of logic in order to understand and defend Christianity. Abelard compiled a book called *Sic et Non (Yes and No).* It consisted of the conflicting views of theological authorities on various religious problems and principles. The work became an influential textbook in the medieval philosophical system called Scholasticism (see Scholasticism). Abelard also wrote an important book on ethics and *The Story of My Misfortunes,* a revealing autobiography. William J. Courtenay

Aberdeen, *AB uhr DEEN* (pop. 201,099), is the third largest city in Scotland. Only Glasgow and Edinburgh have more people. Aberdeen lies on the east coast of northern Scotland, along the North Sea and between the River Dee and River Don (see Scotland [political map]). Sometimes called the *Granite City,* Aberdeen has many office and apartment buildings made of gleaming gray granite. It has long been the main port and distribution center for products of northern Scotland. Its economy is based on trade and other service industries.

Aberdeen dates from the 1100's. Much of the modern city was laid out during the late 1700's and 1800's. During the 1800's, Aberdeen became the marketing center for the surrounding agricultural area, and it developed fishing, granite, and textile industries. Since the 1970's, the production of petroleum in the North Sea has brought new growth and prosperity to Aberdeen. The city has become the headquarters for businesses related to petroleum production. Thousands of new jobs have been created by this economic activity. A. S. Mather

Aberdeen and Temair, *AB ur DEEN, tuh MAIR,* **Marquess of** (1847-1934), a British politician, served as governor general of Canada from 1893 to 1898. In 1896, he set an example for future governors general when he refused to approve last-minute political appointments recommended by outgoing Prime Minister Sir Charles Tupper.

Aberdeen was born in Edinburgh, Scotland. His given and family name was John Campbell Hamilton-Gordon. He became the seventh Earl of Aberdeen in 1870. Lord Aberdeen attended St. Andrews University and Oxford University. He began his political career as a Conservative but later joined the Liberal Party. Aberdeen was the chief British administrator in Ireland in 1886 and from 1905 to 1915. He became a marquess in 1916. Aberdeen and his wife wrote a book about their life called *We Twa* (1925). Jacques Monet

Aberdeen Proving Ground, *AB uhr DEEN,* Maryland, is the United States Army's center for ordnance activities. The Army tests vehicles, bombs, guns, and other ordnance there. The post is the home of the Army Ordnance Center and School, the Army Test and Evaluation Command, and the Chemical Research Development and Engineering Center. It also has laboratories for ballistic research, development and proof services, ordnance disposal, and ergonomics (see Ergonomics). The post covers about 73,000 acres (29,000 hectares) and extends about 18 miles (29 kilometers) along the upper part of Chesapeake Bay near Aberdeen. It was established in 1917. It is recognized as one of the leading military testing and research facilities in the world.
Steve E. Dietrich

Abernathy, Ralph David (1926-1990), was an American civil rights leader. Abernathy served as president of the Southern Christian Leadership Conference (SCLC) from 1968 to 1977. He succeeded Martin Luther King, Jr., who was murdered. In 1955 and 1956, Abernathy helped King lead a bus boycott in Montgomery, Alabama, to protest racial discrimination (see King, Martin Luther, Jr. [The early civil rights movement]). He and King helped organize the SCLC in 1957. Abernathy became the SCLC's vice president at large in 1965. In May 1968, he led the "Poor People's March" on Washington, D.C., which dramatized problems faced by poor people.

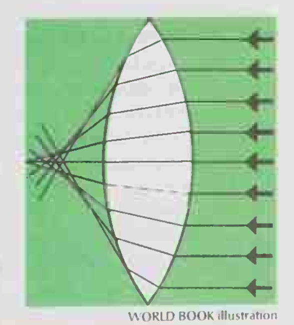
Elaine Tomlin
Ralph David Abernathy

Abernathy was born in Linden, Alabama. He earned a B.S. degree at Alabama State College and an M.S. degree at Atlanta University. He became a Baptist minister in 1948. Abernathy wrote *And the Walls Came Tumbling Down: An Autobiography* (1989). C. Eric Lincoln

Aberration, in optics, is the failure of a lens or mirror to produce an image that is sharply focused and has the same proportions as the object being viewed. There are three main kinds of aberration: (1) *point aberration,* (2) *distortion,* and (3) *chromatic aberration.*

Point aberration produces a fuzzy image by failing

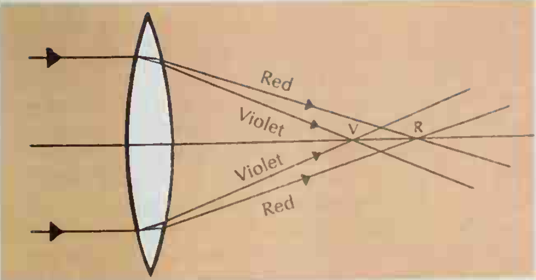
to focus light to a point. The three primary types of point aberration are (1) *spherical aberration,* (2) *astigmatism,* and (3) *coma.*



Spherical aberration occurs in a lens in which one or both sides are curved like a portion of the surface of a sphere. A spherical surface is easy and inexpensive to produce. As a result, a typical lens in a camera, a pair of binoculars, or a small telescope is a piece of glass with spherical surfaces. This kind of lens focuses light well enough for those applications.

To understand spherical aberration, imagine that parallel rays of light strike a lens as shown in the accompanying illustration. If there were no aberration, all the rays would come to a focus at a point on the other side of the lens. But because of aberration, rays that pass through different parts of it come to a focus at different points. All the points are located along the *optical axis,* an imaginary line through the center of the lens. Rays that pass through the lens near its center come to a focus at a point relatively far from the lens. Rays that pass through the lens near its edge come to a relatively close focus. An inward-curving spherical mirror produces spherical aberration in a similar way.

Aberrations are not necessarily a result of manufacturing errors. For example, even a lens with perfectly spherical sides could not focus all parallel rays that pass through it to a single point.



In astigmatism, light comes to a focus as a line, rather than a point. In coma, the light focuses in the shape of a cone. Astigmatism and coma make the image blurry at its edge but not its center.

Distortion results when a lens or mirror focuses light at an incorrect distance from the optical axis. The image will appear either stretched or compressed near the edges.

WORLD BOOK illustration

Spherical aberration occurs in a lens because light rays that pass through the lens at different distances from its center come to a focus at different distances from its edge.

WORLD BOOK illustration

Chromatic aberration occurs because a lens focuses different colors of light at different points—violet light at the nearest point, red at the farthest, and the other colors at points in between.

Chromatic aberration occurs in lenses but not in mirrors. It occurs because a lens focuses light rays of different colors at different distances. The distance to the focal point of a ray of light depends upon the *wavelength* of the light. Wavelength is the distance between successive crests of a light wave. Each color has its own wavelength. From the longest wavelength to the shortest, the colors of visible light include red, orange, yellow, green, blue, and violet.

In *longitudinal chromatic aberration,* a lens focuses the different colors at different points on the optical axis. Violet light comes to a focus that is closest to the lens. Then comes the focal point for blue light, then the point for green, and so forth. In *lateral chromatic aberration,* focal points are also offset above and below the optical axis—red the least, violet the most. W. Thomas Roberts, Jr.

See also **Lens; Mirror; Parabola; Telescope.**

Abidjan, *AB ih JAHN* (pop. 1,930,000), is the largest city of Côte d'Ivoire and one of the busiest seaports in western Africa. The city lies along a lagoon. A canal connects the lagoon with the Gulf of Guinea, an arm of the Atlantic Ocean (see **Côte d'Ivoire** [map]).

Abidjan has many high-rise office and apartment buildings and single-family houses. But it also has areas of overcrowded slums, especially in the suburbs. Its port is a center of West African import and export activities. Products made in the city include automobile parts, beer, and soap. Businesses in Abidjan also process cacao beans, coffee beans, and palm and vegetable oils.

In the late 1800's, France took control of Abidjan and the rest of Côte d'Ivoire. In 1934, Abidjan became the capital. Côte d'Ivoire gained independence from France in 1960. In 1983, the country's legislature approved a proposal allowing the capital to be moved from Abidjan to Yamoussoukro. Robert I. Rotberg

Abilene, *AB uh LEEN* (pop. 6,543), a city in east-central Kansas, is a railroad shipping center for crops raised in the east-central part of the state (see **Kansas** [political map]). Abilene is the seat of Dickinson County.

Between 1867 and 1872, cowhands drove longhorn cattle over the Chisholm Trail to Abilene, where the stock was loaded and shipped to Eastern markets. Probably the biggest year was 1871, when 5,000 cowhands and 700,000 head of cattle came to Abilene from Texas. Wild Bill Hickok became famous as a "two-gun marshal" of Abilene.

President Dwight D. Eisenhower grew up in Abilene. The city is the site of the Eisenhower Center. The center includes Eisenhower's boyhood home, the Eisenhower Museum, Eisenhower Library, and the Place of Meditation, where Eisenhower is buried. The city has a council-manager form of government. James R. Shortridge

Abnormal psychology is the scientific study of psychological disorders. These disorders affect the way people feel, think, speak, and behave. The field of abnormal psychology is sometimes called *psychopathology.*

Standards of normal and abnormal behavior differ from society to society and change as social conditions and customs change. For example, the practice of severely beating children to discipline them was considered normal behavior for many centuries. Today, many people consider such behavior abnormal and cruel.

Studies in abnormal psychology are conducted mainly by clinical psychologists, psychiatrists, and social workers. These experts collect data by such means as personality and intelligence tests, experiments, and case studies. One kind of case study, an *idiographic study,* describes the behavior and thought patterns of one person. Another type, called a *nomothetic study,* examines the behavior and thought patterns common to many people who suffer the same disorder.

Theories of abnormal psychology describe mental illnesses, suggest their possible causes, and propose certain methods of treating them. These theories can be divided into four main groups or schools: (1) biophysical, (2) intrapsychic, (3) existential, and (4) behavioral.

Biophysical theories emphasize the importance of underlying physical causes of psychological disturbances. Such disturbances include two main groups: (1) those due to a medical condition, such as a disease or injury, and (2) those related to the use of a drug or medication. In these disorders, the condition, drug, or medication is believed to cause mental problems by affecting the brain or other parts of the nervous system. Biophysical theorists think such factors also underlie mental disturbances whose causes have not yet been identified. They believe many disturbances result from inherited physical defects.

Biophysical therapists treat mental disorders mainly with tranquilizers, antidepressants, sleeping pills, and other drugs. They sometimes use electric shock or surgery on the brain or other parts of the nervous system.

Intrapsychic theories focus on the emotional basis of abnormal behavior. Intrapsychic theorists believe that conflicts in early childhood cause people to worry or have other unpleasant feelings throughout life.

Psychologists use the term *neurotic* to describe people who sometimes behave abnormally but can usually cope with everyday problems. Individuals who lose track of reality are called *psychotic.* Some psychotics believe in very unrealistic ideas called *delusions.* They may also think perceptions such as "hearing voices" or "seeing visions," called *hallucinations,* are real.

A treatment called *psychoanalysis* is often used to help neurotics and psychotics understand and resolve their conflicts and anxieties. During psychoanalysis, the patient talks to the therapist, who is called an *analyst.* In one technique, called *free association,* the patient talks to the analyst about whatever thoughts, images, or feelings come to mind.

Existential theories of abnormal behavior stress the importance of current experiences and the person's view of himself or herself. Existential therapists try to help patients gain insight into their feelings, accept responsibility for their lives, and fulfill their potential.

Behavioral theories emphasize the effects of learning on behavior. Behaviorists use a learning process called *conditioning* to change abnormal behavior. In this process, behaviorists treat disturbed people by teaching them acceptable behavior patterns and reinforcing desired behavior by rewards and punishments.

History. Since ancient times, people have attempted to understand and treat mental disorders. Many early societies believed that demons caused abnormal behavior. Later, people came to regard the mentally ill as dangerous persons with insufficient self-control to be normal. Disturbed individuals were imprisoned, sometimes locked in chains, or sent to dismal institutions called *insane asylums.*

During the late 1700's, the idea that abnormal behavior resulted from serious personal problems began to be investigated. People started treating the mentally ill more humanely. In the 1800's, people believed in possible physical reasons for different kinds of mental disorders. A German psychiatrist named Emil Kraepelin became famous for his *Kompendium der Psychiatrie* (*A Textbook of Psychiatry,* 1883). This book classified various mental illnesses according to their specific types of abnormal behaviors.

In the late 1800's and early 1900's, Sigmund Freud, an Austrian physician, developed theories about the effects of unconscious drives on behavior. Freud and his followers laid the foundations for both the intrapsychic school of psychopathology and psychoanalysis. The Freudians became especially known for their use of free association to interpret dreams, analyze memories, and make people aware of their unconscious conflicts.

Later in the 1900's, researchers proposed several other theories and treatments of abnormal psychology. These proposals centered on the relationship of psychological, physical, and social conditions in the individual and society. Leah Blumberg Lapidus

Abolition movement was activity that took place in the 1800's to end slavery. Most abolitionist activity occurred in the United States and Britain, but antislavery movements operated in other countries as well.

In the United States, antislavery activity began in colonial days. During the 1680's, Quakers in Pennsylvania condemned slavery on moral grounds. In the late 1700's, several leaders of the American revolutionary movement, including Thomas Jefferson and Patrick Henry, spoke out against slavery.

The American Colonization Society, founded in 1816, led antislavery protests during the early 1800's. It tried to send freed slaves to Liberia in Africa. The abolitionist Elihu Embree published the first periodicals devoted wholly to the abolition of slavery. He established a weekly newspaper in Jonesborough, Tenn., in 1819 and a monthly publication, *The Emancipator,* which appeared in 1820. In 1831, the abolitionist William Lloyd Garrison began publication of his newspaper, *The Liberator.* Garrison demanded immediate freedom for slaves. The American Anti-Slavery Society, founded in 1833, supported Garrison's crusade. The abolition movement gradually spread throughout the Northern States despite bitter and violent opposition by Southern slaveholders and Northerners who favored slavery. In 1837, a mob murdered Elijah P. Lovejoy, a newspaper editor of Alton, Ill., who had published antislavery editorials.

Many famous abolitionists came from New England. They included Garrison, poets James Russell Lowell and John Greenleaf Whittier, and reformer Wendell Phillips. Others, such as the merchant brothers Arthur and

Lewis Tappan and the reformer Theodore Weld, came from Middle Atlantic or Midwestern states.

Women also played an important role in the abolition movement. Lucretia Mott and the sisters Sarah and Angelina Grimké organized groups and made speeches. Many free blacks also joined the abolitionists. They included James Forten and Robert Purvis, wealthy Philadelphia merchants; Frederick Douglass, a former fugitive slave from Maryland; and Sojourner Truth, a freed slave from New York.

The movement entered a new phase in 1840, when some of its leaders entered politics and founded the Liberty Party. James G. Birney, a former slaveholder born in Kentucky, ran as the party's candidate for president in 1840 and 1844. In 1848, abolitionists became an important element in the Free Soil Party. After 1854, most abolitionists supported the Republican Party.

Even after abolitionists entered politics, they remained more interested in their cause than in political offices. They combined political protest with direct action. Their homes often became stations on the *underground railroad,* which helped slaves fleeing to the free states or to Canada.

After the American Civil War began in 1861, abolitionists rallied to the Union cause. They rejoiced when President Abraham Lincoln issued the Emancipation Proclamation on Jan. 1, 1863, declaring the slaves free in many parts of the South. In 1865, the 13th Amendment to the Constitution abolished slavery in the United States. Large numbers of abolitionists then joined the fight to win social and political equality for blacks.

In the United Kingdom, abolitionists worked to end the international slave trade and to free slaves in the British colonies. Slavery had never flourished in England itself. On the other hand, many English people had become wealthy through the slave trade.

William Wilberforce, a statesman and orator, headed the antislavery movement in England. In 1807, he helped persuade Parliament to pass a bill outlawing the slave trade. In 1833, another bill abolished slavery throughout the British Empire. David Herbert Donald

Abominable Snowman, *uh BAHM uh nuh buhl,* also called *Yeti, YEH tee,* is a creature said to live on Mount Everest and other mountains of the Himalaya range of Asia. Reports of such a creature have also come from remote parts of China, Siberia, and other parts of Asia. According to legend, the Abominable Snowman is a hairy beast with a large, apelike body and a face that resembles that of a human being. It has long arms, and it walks erect on thick legs.

The name Abominable Snowman may have come from a journalist's translation of *metoh kangmi,* a Tibetan name for the creature. The name Yeti was given to it by the Sherpa people of Nepal. The word probably once meant *all-devouring creature.* It may refer to a mountain demon rather than a real creature.

There is no direct evidence that the Yeti exists. Local tribes have reported seeing it, but their stories cannot be verified. Since the 1890's, travelers have reported sightings, and explorers have seen footprints of a large, unknown creature in the snow. In 1951, Eric Shipton, a British explorer, photographed "snowman" tracks near Everest. Several expeditions, including one sponsored by *World Book* in 1960, have searched for the creature. The explorers neither captured nor saw anything that might be the snowman. Scientists of the *World Book* expedition said the tracks may have been made by bears or other animals. They found that the sun can cause such tracks to melt into large footprints. Daniel Cohen

Aborigines, *AB uh RIHJ uh neez,* **Australian,** are the modern descendants of the first people to live in Australia. The word *aborigines* comes from the Latin phrase *ab origine,* meaning *from the beginning.* Spelled with a small *a,* the term refers to any people whose ancestors were the first to live in a country. The group of indigenous Australians who live on islands off the northern tip of Queensland are known as Torres Strait Islanders.

Most scholars believe the ancestors of today's Aborigines first arrived in Australia from Southeast Asia between 50,000 and 120,000 years ago. More than 300,000 Aborigines lived on the continent when European colonists first reached Australia in 1788. These Aborigines spoke about 250 distinct languages with about 600 dialects. Today, most of these languages have been lost. Some Aboriginal languages have between 3,000 and 4,000 speakers today. Many Aborigines speak a local variety of English called *Aboriginal English* or *Creole.*

Most early European colonists considered the Aborigines primitive. Because Aborigines have dark skin, Europeans thought that the Aborigines were inferior to them. When Europeans arrived, Aborigines had complex cultural, political, and economic rules and beliefs. But Europeans did not initially understand or appreciate these elaborate social systems.

During the first 150 years of European settlement, many Aborigines were killed in skirmishes across the frontier, poisoned by settlers, or died of diseases introduced by the Europeans. Others were forced into government or missionary settlements. In the far north of Australia, however, many Aborigines were able to live

somewhat independently through the 1930's. Today, the Aborigines and the Torres Strait Islanders make up about 2 percent of the country's population.

Aboriginal life. Prior to the European colonization of Australia, Aborigines had complex social systems and beliefs that varied across the continent. Most Aboriginal groups were composed of people closely related through descent and marriage. Each group had its own spiritual ceremonies and stories about the origin of the group itself and its territory. Some ceremonies were secret. Men and women often had separate ceremonial practices but also came together in joint ceremonies.

Aborigines had a spiritual relationship to the land through *ancestral beings.* According to Aboriginal beliefs, these beings created the world long ago during a period called the *Dreaming,* or *Dreamtime.* Aborigines believe that these ancestral beings never died but merged with the natural world.

Aboriginal groups did not have a formal government or a single leader. Territorial rights were based on descent, birth, and ceremonial ties to a region. When disputes about the use of the land arose, Aborigines negotiated among themselves to solve the dispute.

The economy of Aboriginal society before European colonization consisted of hunting, fishing, and gathering. Men and boys hunted large sea and land animals, such as kangaroo, emu, and sea turtles. Women and young children collected plants, turtles, lizards, and sea snails, using digging sticks, boomerangs, and clubs. Aboriginal society emphasized sharing food among the larger family group. Aboriginal men and women wore waistbands and ornaments but little other clothing in the warm climate. In colder areas, the Aborigines used kangaroo and possum fur to make cloaks and beds.

Aboriginal men and women crafted bags, baskets, and hunting instruments from bark, root fibers, and many other materials. They often decorated these items with red, yellow, and white *ochres* (pigments) and charcoal. Some groups drew figures of the Dreamtime beings on these items as well as on cave walls, rock surfaces, stones, and wooden planks. Some drawings were part of secret ceremonies.

Aboriginal life today. Aborigines today are Australian citizens. But most still face discrimination and prejudice and are underprivileged economically, socially, and politically. Prior to the 1930's, the government thought that the Aboriginal population would die out as settlers moved onto their land. Children with mixed European and Aboriginal ancestry were separated from their families and placed in institutions, missions, and foster homes. These people became known as the *Stolen Generation.* From the 1930's through the 1960's, the government sought to *assimilate* (incorporate) Aborigines into the country's economic, social, and political life. They discouraged Aboriginal social practices, religious observances, and cultural beliefs.

In the late 1960's, Aboriginal activists fought the government policy of assimilation. In 1976, the government passed the Aboriginal Land Rights (Northern Territory) Act, which allowed Aboriginal groups in the Northern Territory to reclaim their traditional lands. In 1980, the government formed the Aboriginal Development Commission. The commission, which is made up of Aborigines, manages lands regained by Aboriginal groups and makes loans to Aboriginal businesses. Today, Aborigines in Australia blend traditional and contemporary lifestyles and practices. Elizabeth A. Povinelli

Abortion is the ending of a pregnancy before birth. Early in a pregnancy, the fertilized egg that grows and develops is called an *embryo.* After three months of development, it is usually called a *fetus.* An abortion causes the embryo or fetus to die. In a *spontaneous abortion,* also called a *miscarriage,* the fetus passes from the woman's body. Spontaneous abortions may result from such natural causes as an abnormality in the embryo, a hormonal imbalance, a long-term disease, or some other disorder in the woman. In an *induced abortion,* the fetus is purposely removed from the woman's body. This article deals with induced abortion.

Abortion methods. Physicians perform abortions in several ways. During the first trimester of pregnancy, the most common method is *suction curettage,* also known as *vacuum aspiration.* This method involves removing the fetus by suction, then scraping the woman's uterus with surgical instruments called *curettes.*

Abortion can also be caused in the first trimester by a drug called *mifepristone* or *RU-486.* The drug blocks the action of the hormone *progesterone* in the woman's body. Normally, this hormone prepares the woman's uterus to receive and nourish the embryo.

In the second trimester, many doctors use a method called *dilation and evacuation,* or simply *D and E.* In this way, the fetus is taken apart in the uterus and removed. Another method involves adding a salt solution to the *amniotic fluid,* the liquid that surrounds the fetus. The fetus then dies and passes from the woman's body. An abortion also may be performed by adding hormonelike drugs called *prostaglandins* to the amniotic fluid. The drugs cause muscle contractions that expel the fetus.

Induced abortion has been a topic of dispute for hundreds of years. People disagree on two basic questions. One question is whether the law should permit a woman to have an abortion and, if so, under what circumstances. The other is whether the law should protect the unborn. Those who wish to legally limit or forbid abortion describe their position as "right-to-life" or "pro-life." Those who believe a woman should have the right to an abortion refer to themselves as "pro-choice."

Arguments against abortion are generally based on the belief that an abortion is the unjustified killing of an unborn child. Most people who oppose abortion believe that human life begins as soon as a sperm fertilizes an egg. Some believe that human embryos and fetuses should have legal rights and that abortion is actually a form of murder. Many pro-life people believe that legalization of abortion increases the number of irresponsible pregnancies and leads to a disrespect for human life.

The Roman Catholic Church is probably the leading opponent of abortion. Conservative branches of other religions also disapprove of abortion.

Arguments for abortion. Many people would allow abortion under certain circumstances. Some approve of abortion if a woman's life or health is endangered by her pregnancy. Others find abortion permissible if medical tests predict that the child will be born with a serious mental or physical defect. Some people would permit abortion when a pregnancy has resulted from rape or incest. Others believe that a woman should have an unrestricted right to an abortion, especially before the fetus becomes *viable*—that is, capable of living outside the mother's body. Most fetuses become viable after the sixth month of the pregnancy.

People who favor an unrestricted right to abortion during early pregnancy often separate human life from *personhood.* They argue that personhood includes an ability to experience self-consciousness and to be accepted as a member of a community. These people believe fetuses are not persons and thus should not be granted the rights given to persons. Such pro-choice thinkers consider birth the beginning of personhood.

Another pro-choice argument is that legal abortion eliminates many of the illegal abortions performed by unskilled individuals under unsanitary conditions. These abortions cause many women permanent injury or result in their deaths. Also, some argue that women should not have to give birth to unwanted children because the world's population is growing rapidly and natural resources are becoming scarce.

Abortion history. Abortion has been practiced and debated since ancient times. The ancient Hebrews permitted it in cases where the mother's life was at risk.

The early Christian church generally opposed abortion. For hundreds of years, however, the church debated whether abortion might be justifiable before *animation.* Church scholars defined animation as the point at which the fetus received a soul. According to church teachings, animation occurred between 40 and 80 days after *conception* (fertilization). From about the 1300's to the 1800's, abortion before animation became generally accepted in Europe if the pregnancy endangered the life of the mother. If an abortion before animation took place for a less serious reason, many church scholars considered it to be wrong, but not homicide.

In 1869, Pope Pius IX condemned abortion from the moment of conception, but some Catholic church scholars continued to teach that abortions performed to save the mother were morally acceptable. In 1895, the Roman Catholic Church declared that abortion is never justifiable. Today, the Catholic church condemns all forms of *direct abortion—that is, the intentional ending of pregnancy. Current Catholic teaching permits* indirect abortion, *in which the fetus is lost as a side effect of medical treatment designed to save the mother's life.*

Abortion in the United States is a subject of public debate. Opinion polls show that most people think abortion should be legal. These people might disapprove of abortion or disagree with some of the reasons that women seek abortions, but they would permit a legal choice. Some believe only the states—and not the federal government—should regulate or outlaw abortion.

Before the mid-1800's, abortion was not a crime under U.S. common law if it took place before *quickening.* Quickening is the time when the mother first feels the fetus moving. State laws prohibiting abortion began to appear in the 1820's. By 1900, every state except Kentucky had made abortion a serious crime. But some courts refused to impose penalties for early abortion.

By the 1960's, pro-choice organizations in the United States had begun working to change state abortion laws. By the early 1970's, 14 states had laws permitting abortion if the woman's health was in danger or if the woman was a victim of incest or rape.

In 1973, the Supreme Court of the United States delivered a historic decision on abortion in the case of *Roe v. Wade.* The court ruled that states could not forbid a woman to have an abortion during the first *trimester* (three months) of pregnancy. The court also ruled that, during the second trimester, states may regulate abortion only to protect women's health. Once the fetus becomes viable in the third trimester, states may regulate abortion to protect the interests of both women and the unborn. The *Roe v. Wade* decision stated that the U.S. Constitution implies the right of privacy and allows a woman to decide for herself if she will have an abortion.

The 1973 decision also defined when a fetus becomes viable. It stated, "Viability is usually placed at about seven months (28 weeks) but may occur earlier, even at 24 weeks." The court said that states may forbid abortion of a viable fetus except when the abortion is necessary to protect the mother's life or health.

Since the *Roe v. Wade* decision, many groups have organized to oppose abortion and the legislation and court decisions that permit it. These groups include the National Right to Life Committee, the Christian Coalition, and Operation Rescue. Most pro-life groups strongly oppose illegal acts. But some individuals have vandalized, bombed, or set fire to abortion clinics. Others have attacked and killed doctors and other clinic employees.

Pro-choice groups also have expanded their efforts. They contact lawmakers, hold demonstrations, and attack restrictive abortion laws in court. Pro-choice organizations include the National Abortion and Reproductive Rights Action League, the Planned Parenthood Federation of America, and the National Organization for Women.

Since 1973, some Supreme Court rulings have limited the influence of *Roe v. Wade.* One such case was *Webster v. Reproductive Health Services* (1989). The court ruled that states may require doctors to test a fetus's viability before performing an abortion on a woman pregnant for 20 weeks or more. The court also ruled that states may outlaw abortions in public hospitals and prohibit public employees from assisting in abortions.

Following the *Roe v. Wade* decision, the federal government and many state governments began to pay for abortions for poor women under the Medicaid program. Many opponents of abortion objected to this use of government funds. In 1977, the Supreme Court ruled that the government was not obligated to finance abortions considered unnecessary to preserve the mother's physical or emotional health. In 1980, the court said the government had no obligation to pay for even most medically necessary abortions. This ruling upheld a federal law called the Hyde Amendment.

In 1990, the Supreme Court decided that states may require minors to obtain parental or court consent before having an abortion. In *Planned Parenthood of Eastern Pennsylvania v. Casey* (1992), both sides of the abortion dispute asked the Supreme Court to review the ruling in *Roe v. Wade.* The justices upheld the ruling by a vote of 5 to 4. The court also ruled that states may require women seeking an abortion to first receive counseling by a doctor about fetal development and abortion risks. The court also decided that states may require women to wait 24 hours between the counseling and the abortion.

The case of *National Organization for Women v. Scheidler* (1994) was a legal response to incidents at abortion clinics. The Supreme Court decided that protesters who block access to clinics can be prosecuted under federal racketeering laws. In 1994, Congress passed the Freedom of Access to Clinic Entrances Act, which protects abortion clinics and their staff members from violence and blockades.

In *Stenberg v. Carhart* (2000), the Supreme Court ruled that a Nebraska law banning what pro-life activists call *partial-birth abortions* was unconstitutional. The procedure, which doctors call *intact dilation and extraction,* involves aborting a fetus after it has been partially removed from a woman's body. The court stated that the Nebraska law placed an "undue burden" on a woman's right to choose an abortion and did not allow the procedure even to protect a woman's health.

In September 2000, the U.S. Food and Drug Administration approved the sale of the abortion drug mifepristone, marketed by the name Mifeprex. The decision allows women to buy pills through physicians to end pregnancies. Supporters of the drug claimed that it would enable women to end their pregnancies earlier, more safely, and with greater privacy than before. The drug had been available in Europe for more than 10 years.

In other countries, abortion laws differ. Lawmakers in some countries have considered abortion an effective tool for limiting family size and combating poverty. In China, for example, abortions are legal and common because the government allows only a limited number of children per family. Chinese women may have an abortion at any time during their pregnancy. In Russia, abortion is allowed up to the 29th week of pregnancy. Japan restricts abortions to the first 24 weeks of pregnancy. Both Russian and Japanese women are allowed to use abortion as a method of birth control.

In the United Kingdom, an abortion may be performed up to the 24th week of pregnancy. However, it must be shown that continuing the pregnancy would endanger the physical or mental health of the woman or her children. Canadian law permits abortion at any time during pregnancy and for any reason. However, most physicians avoid performing abortions during the later stages of pregnancy and do not offer abortion as a method of birth control. David M. O'Brien

Abraham was the founder of Judaism and the ancestor of both the Arabs and the Jews. The Arabs trace their ancestry to Abraham's oldest son, Ishmael. The Jews consider Abraham their ancestor through another son, Isaac. Abraham, Isaac, and Isaac's son Jacob are called the *patriarchs* (founding fathers) of the Jews.

Many scholars believe that Abraham lived between about 1800 and 1500 B.C. The story of his life is told in Genesis, the first book of the Bible. During his early life, Abraham was called Abram. He was born in the city of Ur, in ancient Mesopotamia (now mostly Iraq). The people of Ur, like most people then, worshiped many gods. However, Abram believed in one God. Abram left Ur and traveled west with his wife, Sarah; his nephew Lot; and other members of his household. At God's command, he went to a land called Canaan (later called Palestine). God told Abram that the land would belong to Abram and his descendants.

Abram settled in Canaan, where God made a *covenant* (special agreement) with him. The covenant promised that Abram would have many descendants and that Canaan would be their "everlasting possession" if they remained faithful to God (Genesis 17:4-8). To symbolize His pledge, God changed Abram's name to Abraham, which means *father of many nations.* God commanded him and all males in his family to be circumcised as a symbol of this covenant (see **Circumcision**).

God repeatedly promised Abraham many children. But he and Sarah remained childless. Following a custom of the time, Sarah gave her maid Hagar to Abraham to bear him a child. Hagar bore Abraham a son, Ishmael.

When Abraham and Sarah were very old, God promised them a son within a year. God also told Abraham that He intended to destroy the cities of Sodom and Gomorrah because nearly all the people were wicked.

Abraham pleaded with God to spare the cities for the sake of the righteous but could not persuade Him to do so. But God saved Lot, who lived in Sodom. The next year, Abraham and Sarah had a son, Isaac.

God later gave Abraham his greatest test of faith and obedience. He commanded Abraham to sacrifice Isaac. Abraham took his son to a mountaintop, laid him on an altar, and prepared to kill him. At the last minute, however, God intervened, stopped the killing, and provided a ram for the sacrifice.

The Bible says Abraham died at an advanced age. According to tradition, he was buried in the Cave of Machpelah in Hebron, in what is now the West Bank region of Southwest Asia. Eric M. Meyers

Absalom. See **David.**

Abscess, *AB sehs,* is a collection of pus within an infected part of the body. Pus contains bacteria, blood plasma, and debris from dead cells. It also contains white blood cells, which the body uses to combat infection. An abscess often appears as a red and swollen lump, which may open and drain. Abscesses may occur in any tissue that becomes infected by bacteria.

When abscesses form, blood vessels *dilate* (expand) and fluid from the blood collects in the injured tissue. Serum and white blood cells help destroy the invading bacteria and their poisons. Abscesses swell because the blood vessels expand and the amount of blood in the infected area increases. An abscess is painful because the pus presses on the nerve endings.

Small superficial abscesses, such as pimples, need no special treatment. Boils, carbuncles, or internal abscesses are treated with antibiotics, such as penicillin, and surgical incision if necessary (see **Antibiotic**). An abscess at the root of a tooth should be treated by a dentist. No abscess, regardless of size, should be squeezed, because bacteria can enter the bloodstream and produce infection elsewhere. David T. Woodley

Absentee voting. See **Voting** (Methods of voting).

Absolute zero is the theoretical temperature at which the atoms and molecules of a substance have the least possible energy. This temperature, which scientists believe is the lowest attainable, equals −273.15 °C, or −459.67 °F. These values are based partly on observations of the relationship between the temperature and pressure of a gas. When the temperature of a gas confined in a fixed volume is lowered, its pressure decreases in direct proportion—as though it would become zero at −273.15 °C.

A temperature scale that has absolute zero for its zero point is called an *absolute temperature scale.* One such scale is the *Kelvin scale,* the international standard for scientific temperature measurement. On the Kelvin scale, absolute zero equals zero kelvin (0 K). The word *degree* and the degree symbol (°) are not used with Kelvin temperature readings.

The Kelvin scale is related to the Celsius scale. A Kelvin temperature can be obtained by adding 273.15 to a corresponding Celsius temperature. For example, 20 °C equals 293.15 K. An absolute temperature scale related to the Fahrenheit scale is the *Rankine scale.* This scale is used in the United States for certain kinds of engineering work. A Rankine temperature is obtained by adding 459.67° to a corresponding Fahrenheit temperature. For example, 68 °F equals 527.67 °R.

Physicists theorize that it is impossible to attain a temperature of precisely absolute zero. But scientists have recorded temperatures of less than 1 trillionth of a kelvin in experiments in which they exposed samples of metal to magnetic forces. Nuclei of the metal atoms reacted to the forces in a way that caused the nuclei to lose energy, thereby becoming extremely cold.

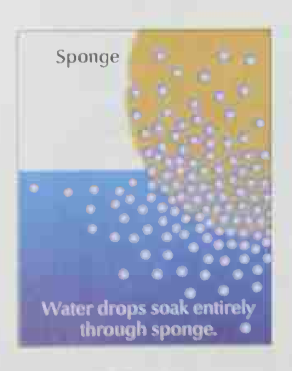
Absolutism, *AB suh loo TIHZ uhm,* is a form of government in which one or more persons rule with power unlimited by law. It includes *dictatorships* and *absolute monarchies.* Most dictatorships are run by a ruler or rulers who seized power by force. In some dictatorships, the government is satisfied to keep the people from revolting while the rulers obtain advantages for themselves. Other dictatorships try to maintain almost complete control over people so as to make great changes in society. Adolf Hitler of Germany and Joseph Stalin of the Soviet Union headed such absolutist governments.



The power of most absolute monarchs is inherited and is supposed to derive from God's will. The monarch may do what he or she wishes. In practice, however, judges, governors, and other officials carry out government functions according to laws, customs, or simply their own judgment. Absolute monarchs ruled ancient China, Egypt, and Rome. Absolute rulers called *czars* governed Russia until the early 1900's. Alexander J. Groth

Absorption and adsorption, *ab SAWRP shuhn, ad SAWRP shuhn,* are processes by which substances take in matter or energy, or both. In *absorption,* the matter or energy taken in becomes distributed throughout the absorbing material. *Adsorption* is the gathering of matter only. The matter collects on the surface of the adsorbing material. It does not enter the interior.

Absorption. There are many familiar examples of absorption. Heavy drapes absorb sound energy. The sound waves make the fibers in the drapes vibrate and rub together. Friction turns the sound energy into heat so the sound cannot be reflected as an echo (see **Insula-**

Absorption

WORLD BOOK illustrations by Mark Swindle

Adsorption

tion [Insulation against sound]). Colored objects and filters selectively absorb light energy. White light is composed of all colors of light. When white light strikes a colored substance, some colors of light energy are absorbed. The absorbed light energy *excites* electrons in the atoms of the colored substance—that is, it raises them to higher energy levels. The substance will transmit or reflect the colors of light that have not been absorbed. Dry earth absorbs water by a process called *capillarity* (see **Capillarity**). The water in a lake absorbs oxygen by dissolving it.

Adsorption. Usually only solid material can act as an adsorbent. The adsorbed matter can be the molecules of a liquid or a gas, or tiny particles of a solid. Adsorption is often highly selective, making it useful for separating or purifying liquids and gases. A charcoal filter adsorbs molecules on the surface of each charcoal particle. Silica gel adsorbs water molecules from moist air and holds them on the surface of each grain. Adsorption releases heat called *heat of adsorption.*

The interaction of adsorbed molecules with the adsorbing surface may be weak or strong. Molecules are weakly held when physical attraction holds them to the adsorbing surface (see **Molecule** [Molecules and matter]). This process is called *physiosorption.* When adsorbed molecules are united chemically with the surface, they are strongly held. This process is called *chemisorption.* In chemisorption, the adsorbed molecules form a single layer. In physiosorption, they may form layers several molecules deep. Emily Jane Rose

Abstract art is a style of art of the 1900's that discards identifiable subject matter. Abstract art is sometimes called *nonobjective art* or *nonfigurative art.*

Abstract art broke with a long tradition in Western culture that considered art a kind of refined illustration. Works of art were often admired because of the importance given to the story or theme they represented. This view began to change in the first decade of the 1900's. At that time, painters allowed the means of imagemaking—brushstrokes, color, and shapes—to overshadow or distort the subject matter. They discovered that the formal characteristics of painting were interesting in their own right.

The first abstract art was produced by painters identified with such movements as Fauvism, Expressionism, Cubism, and Futurism. Their paintings were called "abstract," though subject matter could still be recognized in their work.

After about 1910, some artists eliminated all subject matter in favor of pure forms. Two distinct and opposite theoretical defenses of totally abstract art emerged. The *Spiritualists* worked from the belief that the elements of art could stir the soul and spirit directly. For these artists, references to the material world hindered their ability to convey emotional messages directly and powerfully. Leading *Spiritualists* were Wassily Kandinsky and Kasimir Malevich of Russia and Piet Mondrian of the Netherlands. Kandinsky was a founder of a German art movement known as *Der Blaue Reiter* (The Blue Rider). Malevich was a leader of a Russian movement called *Suprematism.* Mondrian was a member of a Dutch art movement known as *Neoplasticism* or *Die Stijl.*

The other major theory of abstract art was grounded on *Materialism.* It appeared first in the work of the *Constructivist* artists in Russia about 1915. Their art essentially dealt with textures, shapes, colors, and patterns. Their paintings rejected storytelling, poetry, or emotional experiences. To portray objectively the new age and its scientific basis, artists stressed geometric forms; flat, unmodulated colors; and an impersonal approach to their art. Leading Russian *Constructivists* included Vladimir Tatlin, El Lissitsky, Naum Gabo, and Alexander Rodchenko.

The term *abstract art* was originally confusing because it could mean art with altered but still recognizable content, or totally nonfigurative or nonobjective art. However, by the end of World War II in 1945, the term was used primarily as a synonym for art completely without recognizable subject matter. Total abstraction was given wide publicity through the work of the abstract expressionist, or New York School, artists such as Jackson Pollock, Willem de Kooning, Arshile Gorky, Franz Kline, and Robert Motherwell. David Cateforis

Abstract expressionism was a movement in American painting that flourished from the mid-1940's to the mid-1950's. The abstract expressionists developed a revolutionary approach to the nature and purpose of painting. They influenced artists in many countries.

The abstract expressionists rejected many of the cus-

toms and rules of earlier art. They did not paint traditional pictures that told a story or created the appearance of reality. Instead, the abstract expressionists emphasized color, the physical qualities of paint, and the enveloping character of very large paintings.

The abstract expressionist movement was more a philosophical attitude than a particular style. For example, certain abstract expressionist works feature many shapes and thick paint, while others are exceptionally simple and thinly painted. Some of the painters deliberately left portions of the canvas unpainted to provide a contrast with the painted areas. But all the diverse personalities in this movement shared the belief that both the figurative and abstract traditions of modern art could be used freely to express their immediate feelings and their attitude toward life. They maintained that no matter how abstract their paintings appeared, there was always an underlying serious subject.

One of the important abstract expressionists was Jackson Pollock. He placed his canvas on the floor and dripped and splattered the paint from above. This technique led some critics to call Pollock and certain other members of the movement *action painters.* Other leading abstract expressionists included Willem de Kooning, Helen Frankenthaler, Arshile Gorky, Adolph Gottlieb, Philip Guston, Franz Kline, Joan Mitchell, Robert Motherwell, Barnett Newman, Mark Rothko, Clyfford Still, and Bradley Walker Tomlin. Dore Ashton

Abu Bakr. See Muslims (The early caliphs).

Abu Dhabi, *AH boo DAH bee* (pop. 242,975), also called *Abu Zaby,* is the capital of the United Arab Emirates, a confederation of seven Arab states. Abu Dhabi is also the capital of the emirate of Abu Dhabi, which is one of the seven states. Founded in 1761 as a pearl-fishing port, Abu Dhabi lies on an island in the Persian Gulf (see United Arab Emirates [map]). Abu Dhabi has developed rapidly since oil was discovered on the land and in offshore fields in the early 1960's. A development program improved its harbor and constructed buildings, roads, and an international airport. Robert Geran Landen

Abu Simbel, *AH boo SIHM buhl,* **Temples of,** are two ancient Egyptian temples that were carved in a mountainside beside the Nile River in southern Egypt. The pharaoh Ramses II built the temples in the 1200's B.C. The Great Temple extended 200 feet (60 meters) into the mountainside. Four seated figures of Ramses II, each 67 feet (20 meters) high, guarded the entrance. Four figures of Ramses II and two of his wife, Queen Nefertari, stood at the entrance to the other temple.

The temples' original location is now covered by Lake Nasser, which was formed by the Aswan High Dam. In the mid-1960's, the temples were cut into huge blocks and moved to higher ground. About 50 nations contributed funds to this project. Leonard H. Lesko

Abuja, *ah BOOH jah* (pop. 378,671), is the capital of Nigeria. The city lies in a hilly region in the central part of the country. For location, see Nigeria (political map).

Abuja is part of the Abuja Federal Capital Territory, which has an area of about 3,100 square miles (8,000 square kilometers). The city itself covers about 100 square miles (260 square kilometers).

Abuja's major buildings include the National Mosque and the administrative headquarters of the Economic Community of West African States. Many modern roads connect Abuja with surrounding cities and towns. The city is served by an international airport. Huge rock formations lying in or near the city include Aso and Zuma rocks. The official residence of the Nigerian president stands near Aso Rock and is itself nicknamed Aso Rock.

Nigeria created the capital territory in 1976 mainly because Lagos, the former capital, was overcrowded and lacked room for expansion. Construction of the new city of Abuja has occurred since the 1980's. Abuja officially became the new capital in 1991. By the late 1990's, all of Nigeria's government ministries had moved their headquarters from Lagos to Abuja. Ebere Onwudiwe

Acacia, *uh KAY shuh,* is the name of about 1,200 species of trees and shrubs in the pea family. Many acacias grow in tropical and subtropical regions of Australia, Africa, and the Americas. Over 30 species, most of them shrubs, grow in the United States. They are most common from Texas to California. The flowers of most acacias are yellow or white and grow in round or long clusters. Many species have compound leaves consisting of

The catclaw acacia grows in the southwestern United States. The plant has yellow flowers. Its seeds grow in pods.

numerous leaflets. In some species, the leaves grow from wide, flat leafstalks. Other species lack true leaves and have only the leafstalks. Certain species, including the *catclaw acacia* of the southwestern United States and the *bullhorn acacia* of Mexico, have sharp spines. The bullhorn acacia has large, paired hornlike spines that are partly hollow and often inhabited by ferocious ants. These ants attack any other animal that invades the tree. Some acacias produce a gum called *gum arabic* that is used in making foods, drugs, and other products. The bark of various acacias produces *tannin,* a substance used to make leather. In arid regions, acacia leaves and fruits provide food for livestock. J. Massey

Scientific classification. Acacias belong to the pea family, Leguminosae or Fabaceae. The catclaw acacia is *Acacia greggii.* The bullhorn acacia is *A. cornigera.*

Academic freedom is a term that refers primarily to certain rights claimed by professors at universities and colleges. The term also refers to various rights claimed by students at those institutions and by the institutions themselves. During the 1960's, the term academic freedom came into use to describe rights claimed by elementary-school and high-school teachers as well.

For professors, academic freedom means the right to teach, to conduct research, and to write without fear of dismissal. For their students, it means the right to challenge the professors' views without being penalized. For the institutions, it means the right to determine what is taught and what research is conducted on the campus. For teachers, such freedom means a larger share in selecting the contents of courses, and greater freedom to engage in political and social activities.

Academic freedom grew out of freedom of thought and expression, a basic right of any free society. Without such freedom, scholars cannot perform their vital role of seeking and spreading new knowledge. Scholars insist on having the freedom to present the truth as they find it, even if it conflicts with popular belief. They say that creative research is impossible if its findings must be withheld or distorted to agree with established views. This spirit of free inquiry and teaching helps give universities and colleges their unique character.

The chief importance of academic freedom is that society benefits from the knowledge discovered by scholars. Yet, the history of academic freedom is largely the history of the many attacks on it.

Beginnings. The idea of academic freedom developed with the rise of universities in Europe during the 1100's and 1200's. The scholars at those institutions wanted freedom to pursue their studies. The universities governed themselves, and many became famous and powerful. But even the most powerful universities were subject to church control. The church persecuted many scholars whose ideas and teaching contradicted religious beliefs. One such scholar was the Italian astronomer and physicist Galileo. In the 1600's, the church persecuted Galileo for supporting various theories, including the one that the earth moves around the sun.

By the 1800's, the concept of academic freedom had been established in Germany, along with the idea of the university as a research institution. Professors could teach whatever they desired and could undertake any research. Students could study whatever they wanted, subject only to their taking a final examination. Such ideas influenced the growth of American universities.

In the United States, academic freedom has faced a variety of threats. In colonial times, religious intolerance presented the biggest danger to academic freedom. Universities dismissed many teachers whose religious beliefs conflicted with the established views.

During the 1800's, economic and political power became the major source of threats to academic freedom in the United States. Many private universities had wealthy benefactors as trustees, and most state universities had politically appointed trustees. Some trustees felt that the teaching in their universities should agree with their own economic and political views. As a result, a number of professors lost their jobs for teaching certain economic or political concepts. However, most university trustees respected academic freedom.

The 1900's. After World War II ended in 1945, academic freedom in the United States came under attack by many people who feared possible Communist infiltration of universities. An investigation by the Un-American Activities Committee of the U.S. House of Representatives found Communists on the faculty of a few universities. As a result, many people feared that most universities were full of Communists. A number of professors were unjustly accused of supporting Communism and lost their jobs.

In the 1960's, academic freedom faced new challenges—from the campus itself. Many students opposed the U.S. role in the Vietnam War (1957-1975)—and all forms of war as well. They resented having military research conducted on campus. They thought that funds spent for military purposes should go instead to help minority groups gain equality and to eliminate poverty and pollution. Many students also questioned the relationship of some of their courses to current problems. A number of faculty members joined the student protests.

Student unrest brought different types of academic freedom into conflict with one another. Student demands challenged the right of professors to teach and to conduct research. Similarly, student and faculty demands challenged the universities' right to decide what should be taught and what research should be conducted. This clash raised serious issues. For example, what responsibilities accompany the rights of academic freedom? To what extent does a person's academic freedom entitle him or her to interfere with that of others? The future of universities and colleges in the United States depends largely on solutions to these issues.

A. Harry Passow

Academy is the general name for a group of people or an organization that promotes art, literature, science, or some other field of knowledge. Some high schools are also called academies. See also Arts and Sciences, American Academy of; Education (The colonial period); French Academy; National Academy of Sciences.

Academy Award. See Motion picture (table: Academy Award winners).

Academy of Motion Picture Arts and Sciences is an honorary nonprofit organization. It was founded in 1927. Its 5,200 members represent leaders in every phase of filmmaking. Its purposes are to advance the arts and sciences of motion pictures; to foster cooperation in the industry for cultural, educational, and techno-

logical progress; and to recognize outstanding film achievements through the presentation of annual awards called *Oscars.* See also Motion picture (table).

Acadia, *uh KAY dee uh,* was a region in eastern Canada that became the site of the first permanent French colony in North America. French colonists settled there in 1604. Acadia included what are now the provinces of Nova Scotia, New Brunswick, and Prince Edward Island. Also in Acadia were parts of what are now the province of Quebec and the state of Maine. Acadia is best known as the setting for the romantic poem *Evangeline* (1847) by Henry Wadsworth Longfellow, an American poet.

The French explorer Sieur de Monts founded the original settlement in Acadia. Acadia remained a French settlement until the early 1700's, when it became involved in the struggle for control of North America between France and England.

During Queen Anne's War (1702-1713), Port Royal, the seat of the Acadian government, surrendered to the British. The Treaty of Utrecht, which ended the war, gave Acadia to Britain. A dispute arose, however, when France only *ceded* (surrendered) what is now mainland Nova Scotia. The other parts of Acadia tried to remain neutral in the dispute.

In 1755, during the French and Indian War, British officials tried to force the Acadians to take an oath of allegiance to the British king. But the Acadians refused to do so, and between 1755 and 1763 about 10,000 men, women, and children were forced to move to colonies farther south. After suffering much hardship, most of these people in time returned to Acadia and settled in southeastern New Brunswick. Over 350,000 of their descendants still live there. About 4,000 Acadians went to Louisiana, a former French colony in what is now the United States. Descendants of these Acadians are known as *Cajuns.* Many of them still speak a French dialect.

John A. Dickinson

WORLD BOOK map

Location of Acadia

Acadia National Park, *uh KAY dee uh,* was the first national park established in the United States east of the Mississippi River. It lies in Maine on Mount Desert Island, Isle au Haut, and on the Schoodic Peninsula. For the area of Acadia National Park, see National Park System (table: National parks).

Acadia National Park contains several peaks, including Cadillac Mountain (1,530 feet, or 466 meters). Cadillac Mountain is the highest granite mountain on the eastern coast. Forests and lakes make the park an excellent wildlife sanctuary. A marine biological laboratory has been established in the park. Acadia National Park was established on land donated by residents of the island in 1916.

Critically reviewed by the National Park Service

Acanthus, *uh KAN thuhs,* is a group of shrubs or herbs that are found chiefly in Asia, Africa, and southern Europe. They spread from underground stems and sometimes become pests. The flowers vary in color from white to purple and develop on rigid spikes. The large leaves have many narrow, pointed lobes.

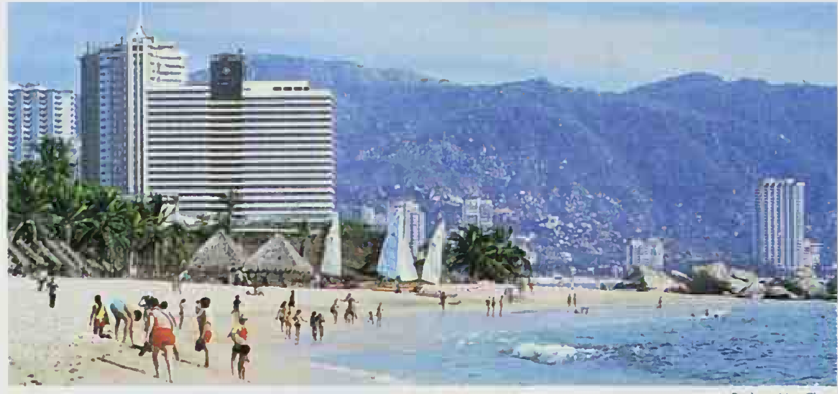
Eric Crichton, Bruce Coleman Ltd.

Acanthus

Acanthus plants prefer rich soil and some shade, and can live with little water. One species grows in semiarid parts of the Southwestern United States.

In architecture, acanthus refers to a leafy decoration that was popular in Greek and Roman times. The design at the top of the Corinthian column is an example of acanthus. See Column.

Melinda F. Denton



Scientific classification. Acanthus plants belong to the acanthus family, Acanthaceae. They are in the genus *Acanthus.*

Acapulco, *AH kah POOL koh* (pop. 721,011), officially known as Acapulco de Juárez, *day HWAH rehz,* is a Mexican port and resort city. Its beautiful scenery and warm, sunny climate make it one of the world's most popular vacation spots. Acapulco lies on forested hills along a deep, natural harbor on Mexico's Pacific coast. The city is about 190 miles (306 kilometers) southwest of Mexico City (see Mexico [political map]).

Acapulco has many activities for vacationers, including sunbathing, swimming, sailing, deep-sea fishing, and water-skiing. People also enjoy the city's fine restaurants and nightclubs. Visitors are thrilled by the divers at the nearby La Quebrada cliffs. These daring divers plunge more than 120 feet (37 meters) from a platform into the water of a rocky cove. The cove is too shallow except when large waves surge in, and so the divers must time their fall to hit one of the waves.

Tourism became Acapulco's leading industry after the city underwent rapid expansion beginning in the 1950's. Acapulco has over 250 hotels and motels.

A small Indian village stood near what is now Acapulco when Spanish explorers arrived there during the early 1500's. The Spaniards founded Acapulco in 1550 as a seaport and built ships there for Pacific exploration and trade. During Spanish rule, Acapulco was the last stop for ships bringing silks and spices from the Philippines. In 1616, Fort San Diego was built to protect Aca-

Barbara Van Cleve

pulco from pirates. The fort was rebuilt in the 1780's after an earthquake and still stands in the center of the city. Nathan A. Haverstock

Acceleration. See Motion (Acceleration); Falling bodies, Law of; Velocity (Acceleration).

Accelerator, Particle. See Particle accelerator.

Accent, *AK sehnt,* in language, is an emphasis placed on a syllable in a word and is often called *stress.* Dictionaries usually indicate an accented syllable by the mark, ', placed after the syllable. A secondary accent can be indicated by two marks, " , or by one light accent mark. Accented syllables can also be shown by capital letters or italics. Where pronunciations are given in *The World Book Encyclopedia,* capital letters are used for the syllable with the primary accent and small capital letters for the secondary accent. See Key to pronunciation at the beginning of the A volume.

The tendency in English is to shift the accent toward the beginning of the word. The accent in the word *re VOKE* shifts toward the beginning in the form *ir REV ocable.* This tendency often causes a change in the language. The accent in the word *BAL con y* was once placed on the second syllable (*bal CON y*).

Words spelled in the same way are sometimes accented on different syllables. This usually means they have different meanings or different usages. The verb of a pair of identical words may have the accent on the second syllable, although the noun or adjective has it on the first. For example, *ab SENT* is the verb, while *AB sent* is the adjective. Accent is important in sentences as well as in words. Marianne Cooley

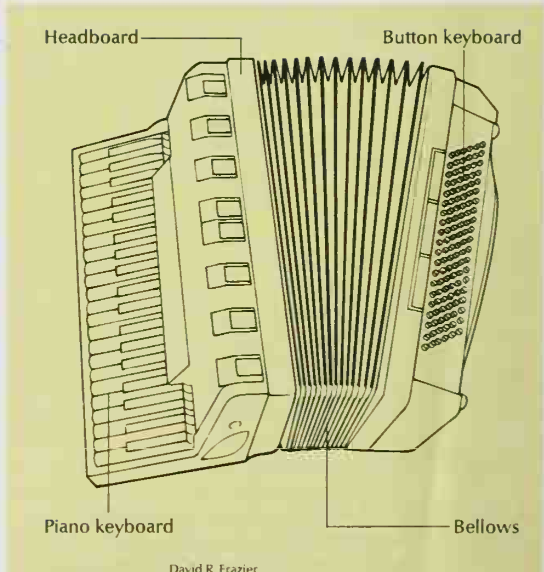
Acclimatization. See Adaptation.

Accommodation, in physiology. See Eye (Focusing).



Accordion is any of a family of portable reed instruments with bellows suspended in front of the player by shoulder straps. The player stretches and compresses the bellows by hand. These movements force air past metal reeds, making them vibrate and produce sounds. The right hand plays buttons or keys arranged in the order of the scale, like piano keys. The left hand presses buttons that produce single tones and chords. In many countries, accordions are used in folk and popular music. Cyrillys Damian invented an accordion in Vienna in 1829. But the principle had been known for centuries in China. Valerie Woodring Goertzen

See also Concertina.

Accounting is a system of gathering, summarizing, and communicating financial information for a business firm, government, or other organization. Accounting, also called *accountancy,* enables decision makers to interpret financial information and use the results in planning for the future. For example, such data tell executives which products or departments are doing well and which poorly.

Business people often call accounting the "language of business" because they use accounting data in com-

The accordion is played by stretching and compressing the bellows while the fingers press various keys and buttons.

municating about a firm's activities. Information provided by accountants helps managers and other executives understand the results of business transactions and interpret the financial status of their organization. With this knowledge, managers can make informed decisions about such matters as production, marketing, and financing. Charities, churches, colleges, government agencies, and other nonprofit organizations also use accounting to keep track of their financial situation.

Bookkeeping is a small but important part of accounting. It involves recording financial transactions and keeping other financial records. Most repetitive bookkeeping is done with computers.

Financial reports

In the United States, publicly owned businesses are required by law to issue financial reports. These reports are used by investors; officials of banks, government agencies, and labor unions; and others interested in a firm or its industry. Accountants prepare the reports, which provide summaries of a company's financial condition. Most companies issue quarterly reports. All firms use similar accounting procedures so that the reports can be compared. In the United States, the Financial Accounting Standards Board (FASB), a group of professional accountants, establishes these procedures, which are called *accounting principles.*

The most important financial reports include *balance sheets, income statements,* and *statements of cash flows.* A balance sheet shows a company's assets, liabilities, and net worth. An income statement is a report of a firm's revenue and expenses during a certain period. The bottom line of an income statement shows whether the company had a net profit or a net loss for that period. A statement of cash flows shows the amounts of money flowing into a company and out of it as a result of its operating, investing, and financing activities.

Organizations that do not seek a profit need many of the same kinds of financial reports. For example, private schools must keep track of their tuition income and their expenses. A government agency may wish to compare the cost of a program with the benefits. Possible donors to a charity may like to see how previous donations were used.

Fields of accounting

Accountants may be classified by the type of organization for which they work. For example, *business accountants* are employed by all types of companies. A small firm may have one general accountant who handles all financial records. But a large corporation may have many accountants for the various duties involved.

Organizations or individuals may hire professional *public accountants* for occasional tasks or special accounting services. Most public accountants have passed a state examination and obtained a license to practice as *certified public accountants* (CPA's). Such accountants are called *chartered accountants* in Canada, the United Kingdom, and some other countries.

Most accountants specialize in a field of accounting. The major fields include financial accounting, management accounting, tax accounting, auditing, and management consulting services.

Financial accounting involves the preparation of a business's financial statements, mainly for users outside the business. These reports are used by owners and potential owners of a business and by people who have loaned a company money. Some government agencies that regulate business and the stock market require companies to submit financial statements to them.

Management accounting helps managers plan and control a company's operations. Accountants prepare budgets to express management's goals in financial terms. After a budget has been adopted, *performance reports* compare actual results with the budget. *Cost accountants* help management keep track of how much it costs a company to make the product, or provide the service, it sells.

Tax accounting consists of preparing tax returns for organizations or individuals and determining the taxes involved in proposed business transactions. Tax accountants suggest ways to save money on taxes. They must have a thorough knowledge of the tax laws that affect their clients or employers. They also must know the details of court rulings in a wide variety of tax cases.

Auditing involves the examination of an organization's financial statements and records. CPA auditors from outside the organization provide assurance that the organization's statements present financial information fairly and that they follow generally accepted accounting principles. People use such statements when deciding which companies to invest in and lend money to.

Internal auditors are employees of an organization who make sure that organization follows the accounting procedures management wants. They also seek ways to increase efficiency and reduce waste.

Management consulting services consist of a variety of activities that many accountants perform. These services include the design and installation of computerized financial information systems, assistance in setting up employee pension plans, and the planning of an individual's personal finances.

Careers

The number of jobs in many accounting fields is growing. Increasingly sophisticated management techniques demand information that can be provided most efficiently by accountants. Accounting requires the ability to gather data, analyze problems completely, and present conclusions clearly.

A college education with a major in accounting is good preparation for an accounting career. Many organizations prefer accountants with a master's degree in accounting or management. Many accountants become certified public accountants because they wish to practice public accounting or to have the distinction of earning a CPA certificate.

Most accountants work for business companies or government agencies. Some have jobs with foundations, hospitals, labor unions, universities, or other nonprofit organizations. Many CPA's practice in public accounting firms that provide a wide range of services. In the United States, four large public accounting firms dominate the accounting industry. These four firms are Deloitte Touche Tohmatsu; Ernst & Young; KPMG International; and PricewaterhouseCoopers. Robert M. Keith

Accra, *uh KRAH* or *AK ruh* (pop. 964,879; met. area pop. 1,420,065), is the capital and largest city of Ghana. It lies on the northern coast of the Gulf of Guinea. For the location of Accra, see **Ghana** (map). Accra's transportation facilities include a railroad and an international airport. The city's industries include the production of tile and brick and the processing of diamonds and lumber. The University of Ghana is located in Legon, a residential area north of the city.

Accra was established by the Ga people by the mid-1600's. It was a center of the African slave trade from the 1500's to the mid-1800's. European nations competing for slaves built several forts in Accra. In 1923, a railroad linking Accra and the interior added to the city's economic importance. Samuel Decalo

Acculturation. See **Culture** (Contact with other cultures).

Ace is a pilot who shot down at least five enemy aircraft during a war. By military custom, most air forces award a *victory* or a *kill* only when a pilot causes an enemy aircraft to crash or destroys it in flight. In addition, most air forces require confirmation by an eyewitness or by videotape or film of the incident. Because of human error and differences in counting practices, the actual number of aircraft a pilot has shot down can be higher or lower than a force's official tally of victories.

The custom of qualifying aces originated during World War I (1914-1918). A minimum of five victories became widely used as the standard for becoming an ace.

The leading aces of World War I became national heroes. The top ace of the war was Baron Manfred von Richthofen of Germany, who was known as the *Red Baron* or *Red Knight.* Von Richthofen shot down 80 enemy aircraft before he was killed in action in 1918. Aces from other countries included Captain René Fonck of France, with 75 kills; and Major Edward Mannock of Britain, with 61. Canadian Major Billy Bishop claimed 72 kills, but some historians have questioned that number. The top American ace, Captain Eddie Rickenbacker, had 26 kills.

During World War II (1939-1945), Major Erich Hartmann of Germany was the top ace, with 352 victories. In addition, thousands of other German aviators qualified as aces by U.S. standards, many with 100 victories or more. Warrant Officer Hiroyoshi Nishizawa of Japan destroyed or damaged 87 Allied planes. Major Richard I. Bong of the U.S. Army Air Force became the leading American ace, shooting down 40 Japanese planes. Six other Americans also equaled or surpassed Eddie Rickenbacker's World War I record. The Soviet Union's top ace, Major Ivan Kozhedub, claimed 62 victories from 1942 to 1945.

During the Korean War (1950-1953), U.S. Air Force Captain James Jabara became the first jet-to-jet combat ace, destroying 15 enemy jets. During the Vietnam War (1957-1975), two American pilots became aces.

Acerola, *AS uh ROH luh,* is the fruit of a bushy tree that grows 10 to 15 feet (3.0 to 4.6 meters) tall. It is native to the West Indies and parts of Mexico, Central America, and northern South America. The tree has deep roots and grows well even in poor soil, if there is enough rain.

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

Acerola is the nutritious fruit of a bushy tree that is also called the acerola. The ripened fruit resembles a deep red cherry.

The acerola is also called the *Puerto Rican, West Indian,* or *Barbados cherry.* The fruits are about the size of cherries. When ripe, acerolas have a deep red color and soft flesh. Most have a tart flavor.

The acerola ranks as the richest known natural source of vitamin C (ascorbic acid). The vitamin C content varies in different varieties and under different environmental conditions. Green fruits contain more vitamin C than ripe fruits. The edible part of the acerola has about 1 to 4 percent ascorbic acid. In other kinds of fruits, even 0.06 percent ascorbic acid is high. Jelly and juices made from acerolas retain the fruit's high vitamin C content.

The acerola was eaten by Indians long before the Europeans came to the Western Hemisphere. During the late 1940's, commercial canners began to use the acerola in fruit juice mixes. Today, the fruit is an important crop in Puerto Rico. Philip J. Ito

Scientific classification. The acerola belongs to the malpighia family, Malpighiaceae. The scientific name is *Malpighia emarginata.* In the past, it was often classified as *M. glabra* or *M. punicifolia.*

Acetaminophen, *uh SEET uh MIHN uh fuhn,* is a commonly used drug that relieves pain and reduces fever. Many people take acetaminophen instead of aspirin because they are allergic to aspirin, have stomach ailments, or use *anticoagulants* (substances that prevent or slow blood clotting). Acetaminophen, unlike aspirin, does not irritate the stomach or interfere with blood clotting. However, acetaminophen cannot reduce inflammation nearly as well as aspirin. Therefore, it is not as useful in treating inflammatory conditions, such as arthritis or rheumatic fever.

Acetaminophen can be purchased without a prescription under many trade names, including Tylenol. Doctors advise people to be extremely careful not to take more than the recommended dose. The drug can cause liver damage that may, in some cases, progress to liver failure and death.

Acetaminophen was first used in medicine in 1893. However, it gained widespread use only after 1949,

when scientists discovered that another popular drug, *phenacetin,* is converted to acetaminophen in the body. Acetaminophen proved to be as effective as phenacetin but less toxic. Eugene M. Johnson, Jr.

Acetate, *AS uh tayt,* is a manufactured fiber produced from wood. It is delicate and resembles silk in feel and appearance. Acetate is used primarily in textiles, especially draperies, linings for clothing, and formal wear.

In a common method of acetate production, called *acetylation,* pulped wood is mixed with acetic acid, acetic anhydride, and sulfuric acid. The mixture is added to water, and white flakes of *cellulose acetate* form. The flakes are dried and dissolved in acetone. The resulting solution, pure or with dyes added, is then forced through a *spinneret* (plate with tiny holes), forming a continuous filament. Acetate filaments can be spun into threads and yarns of different thicknesses and textures.

Acetate's naturally shiny finish can be dulled by adding titanium dioxide to the solution before forcing it through the spinneret. Acetate melts when exposed to temperatures of 350 °F (177 °C) or higher, so acetate fabrics must be ironed at low settings. Richard V. Gregory

Acetic acid, *uh SEE tihk,* is an important organic acid and industrial chemical. It gives vinegar its sour taste. Vinegar used in the home contains about 5 percent of the acid. Pure acetic acid is called *glacial acetic acid* because it solidifies at 62 °F (17 °C), the temperature of a cool room. When diluted with water, it is known simply as acetic acid. See **Vinegar**.

Georg Stahl, a German chemist, first isolated glacial acetic acid from vinegar in 1700. Commercially, the acid is usually produced by such chemical processes as the oxidation of acetaldehyde with air in the presence of catalysts. Acetaldehyde is itself formed from the oxidation of ethylene obtained from petroleum.

One of the chief uses of acetic acid is as an intermediate for making other chemicals. Manufacturers convert it into acetic anhydride and acetate esters. Acetic anhydride is used to make acetate fibers and cellulose acetate, a plastic. Ethyl acetate is an important ester used as a solvent for varnishes and in nail polish remover. As a reagent, acetic acid is used to make synthetics, rubber, and aspirin and other pharmaceuticals.

Acetic acid is a colorless liquid with a sharp, irritating odor. It is a caustic substance, and concentrated forms of it can cause severe burns. The chemical formula of acetic acid is CH_3COOH. Robert J. Ouellette

Acetone, *AS uh tohn,* is an important industrial chemical. Its chief use is in making other compounds. Industry prepares acetone commercially from isopropyl alcohol, using brass or copper catalysts. Acetone can also be obtained from corn and other starchy products by fermenting them with a special bacteria and then distilling them.

Acetone also forms in the body of a diabetic person. Its presence in urine is one symptom of the disease.

Acetone dissolves many substances, including gums, oils, resins, fats, and cellulose. Industry uses acetone in paints, varnish removers, nail polish and nail polish removers, and some polishes and lacquers.

Acetone is a clear, colorless, flammable liquid with a fruity odor. It mixes easily with water. Its chemical formula is CH_3COCH_3, and it boils at 56.2 °C (133.2 °F).

Suzanne R. Abrams

See also **Acetylene**.

Acetylene, *uh SEHT uh leen,* is a colorless, flammable gas used for welding and for preparing other chemical compounds. Its chemical formula is C_2H_2. Acetylene is poisonous if inhaled. It also forms explosive mixtures with air. Edmund Davy, an English chemist, first produced acetylene in 1836. The gas was forgotten until 1860, when the French chemist Marcelin Berthelot discovered a way to synthesize the gas from carbon and hydrogen, using an electric arc.

Acetylene mixed with oxygen produces a flame that reaches a temperature of about 6000 °F (3316 °C). This flame, called the *oxyacetylene flame,* is used to weld and cut metals. In welding, the edges of the metal are melted by the flame and then fused together (see **Welding**). In cutting, the metal to be cut is heated but not melted by the oxyacetylene flame. Then a fine stream of oxygen is sprayed onto the metal. The oxygen burns through the metal, leaving a clean-cut edge. Acetylene also serves as a raw material in the preparation of certain chemical compounds used to manufacture plastics. In addition, acetylene is used in the manufacture of vitamins.

Acetylene may be produced commercially by creating a chemical reaction between calcium carbide and water. It is also made in industry by decomposing methane at high temperatures. Acetylene is stored in cylinders under high pressure. If not properly handled, the compressed gas can break down chemically and explode. To prevent explosions, acetylene is dissolved in acetone in special cylinders. Suzanne R. Abrams

Acetylsalicylic acid. See **Aspirin**.

Achaeans, *uh KEE uhnz,* were people of ancient Greece who lived in the *Peloponnesus* (Greece's southern peninsula), in east-central Greece, and on the islands of Crete, Rhodes, Cephalonia, and Ithaca. The term *Achaeans* appears in the epic the *Iliad* to identify the Greeks who fought in the Trojan War. Achaeans are also mentioned in Hittite documents from the 1300's and 1200's B.C., found in what is now Turkey. Some Achaeans may have taken part in sea raids on Egypt in the early 1100's B.C. Later in the 1100's B.C., Dorian invaders swept across Greece and drove the Achaeans to a region in the northern Peloponnesus. This region later became known as *Achaea.*

In the 300's B.C., 12 Achaean cities formed a confederation that was known as the *Achaean League.* The league played an important part in Greek politics, opposing first the Macedonians and then the Romans. The Romans conquered Greece and broke up the league in 146 B.C. Norman A. Doenges

See also **Aeolians; Dorians; Iliad.**

Achebe, *ah CHAY bay,* **Chinua,** *CHIHN oo ah* (1930-), is a leading Nigerian author best known for novels that explore the psychological and social impact of Western colonialism on traditional African societies. Achebe, who writes in English, also deals with aspects of African life after Africans gained their independence from European colonial powers in the mid-1900's. Critics have praised the simplicity of Achebe's language, his use of proverbs and folklore, his irony, and his objectivity in presenting complex issues.

Achebe gained international recognition with his first novel, *Things Fall Apart* (1958). The work portrays the influence of colonial European missionaries and govern-

ment on a west African tribe during the late 1800's. Achebe continued this theme in the novel *Arrow of God* (1964). He dealt with late colonial and postcolonial life in Africa in the novels *No Longer at Ease* (1960), *A Man of the People* (1966), and *Anthills of the Savannah* (1987).

In addition to his novels, Achebe has published the short-story collections *The Sacrificial Egg* (1962) and *Girls at War* (1973). He has written a number of children's books, including *Chike and the River* (1966), *How the Leopard Got His Claws* (1972) as co-author, and *The Flute* and *The Drum* (both 1977). His poetry has been collected in *Beware, Soul-Brother* (1971) and *Christmas in Biafra* (1973). Many of his essays have been published in *Morning Yet on Creation Day* (1975), *The Trouble with Nigeria* (1983), and *Hopes and Impediments* (1988).

Albert Chinualumogu Achebe was born in Ogidi, Nigeria, which was then a British colony. He attended University College in Ibadan from 1948 to 1953. Achebe worked in broadcasting in Nigeria from 1954 to 1966 and was professor of English at the University of Nigeria from 1976 to 1981. He has also taught at several universities in the United States. Peter Nazareth

Acheron. See Hades.

Acheson, *ACH ih suhn,* **Dean Gooderham** (1893-1971), was United States secretary of state under President Harry S. Truman from 1949 to 1953. Before he held that position, Acheson had served as undersecretary to three secretaries of state—Cordell Hull, James F. Byrnes, and George C. Marshall.

In the Acheson-Lilienthal Report of 1946, Acheson urged international control of nuclear power. He negotiated the treaty that led to the North Atlantic Treaty Organization (NATO) in 1949. He began carrying out the Marshall Plan in 1948. This plan aided the economic recovery of Europe after World War II (see **Marshall Plan**). Acheson began much of the Truman Doctrine to protect Greece and Turkey from Soviet imperialism (see **Truman, Harry S.** [The Truman Doctrine]).

Senator Joseph McCarthy and other people accused Acheson of "coddling" Communists in the State Department. His critics also blamed him for encouraging the Communist invasion of South Korea in 1950 and for the Communist victory in China in 1949. But his supporters have argued that Chiang Kai-shek, leader of the Chinese government, lost to the Communists because he lacked the support of his own people, and not because of lack of U.S. support. Most historians have also rejected the other charges against Acheson.

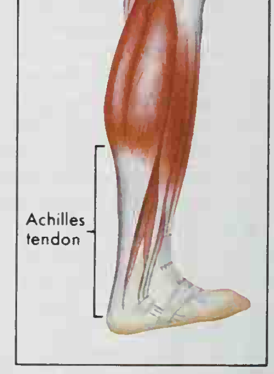
Acheson wrote many books, including *Present at the Creation: My Years in the State Department* (1969), which won the 1970 Pulitzer Prize for history. He was born in Middletown, Connecticut. William E. Pemberton

Achilles, *uh KIHL eez,* in Greek mythology, was the best Greek warrior in the Trojan War. In the 10th year of that war, the Greeks defeated the city of Troy.

The events in Achilles's life are legends but may have some historical basis. Achilles was the son of Peleus, the king of Phthia in Thessaly, and Thetis, an immortal sea nymph. Soon after Achilles was born, Thetis dipped him in the River Styx, whose water would make him invulnerable, like a god. However, the immortalizing water did not touch the heel by which Thetis held him.

When the Trojan War began, Agamemnon, the commander of the Greek forces, sent soldiers to recruit Achilles into the Greek army. Thetis feared her son, who was just approaching manhood, would be killed in battle. She sent him, disguised in women's clothing, to live with King Lycomedes on the island of Skíros. But Odysseus (Ulysses in Latin), who was a cunning Greek general, saw through the disguise, and Achilles joined the army.

During the last year of the war, Achilles quarreled with Agamemnon, who took away Briseis, a young woman Achilles had captured as a prize of war. In anger, Achilles refused to fight any longer and, without him, the Greek forces began to lose. Achilles allowed Patroclus, his best friend, to join the battle wearing his armor. Patroclus was slain by Hector, the greatest Trojan warrior. Enraged, Achilles returned to the battlefield, slaughtering everyone in his path. He eventually killed Hector, aided by the goddess Athena. According to some stories, Hector's brother Paris shot an arrow into Achilles's heel, and Achilles died from the wound.



Nancy Felson

Achilles tendon, *uh KIHL eez,* is the tendon at the back of the ankle. It attaches the muscles of the calf to the heel bone and is one of the strongest tendons in the body. The name *Achilles tendon* comes from the legend of Achilles, a Greek hero killed by an arrow in the heel.

The Achilles tendon may rupture as the result of a powerful upward movement of the foot or a blow to the calf when the calf muscles are contracted. This injury most commonly occurs in people over the age of 30 who compete in sports that involve running. Complete rupture frequently is accompanied by a snap, severe pain, and the inability to push off or stand on the toes. As soon as possible, ice should be applied to the back of the ankle, and the leg should be raised and immobilized. Surgery may be necessary to sew the tendon together. The person should stay off the injured leg for up to two months before beginning a program of gradual stretching and strengthening exercises. Full recovery may take a year or more.

John R. Conway III

WORLD BOOK illustration by Charles Wellek

Achilles tendon

Acid is any of a group of chemical compounds with certain similar properties. Solutions of acids have a sour taste and produce a prickling or burning sensation if they come into contact with the skin. They dissolve many metals and turn blue litmus paper red. Chemical compounds called *bases* or *alkalis* neutralize acids.

Many acids occur naturally and some are essential for life. For example, *hydrochloric acid* (HCl) is produced in the stomach of most people and helps digestion. Acids are also used widely in industry, and they are a part of a large number of foods and beverages. But many acids are poisonous, and strong acids can cause severe burns.

Chemists use several definitions to describe the behavior of acids. When water is the solvent, an acid is often defined as a compound that dissolves to produce *hydrogen ions* ($H+$) in solution. A hydrogen atom consists of one proton, which has a positive electric charge, and one electron, which has a negative charge. A hydrogen ion is the proton that remains when the atom loses its electron. In solution, the proton is closely associated with solvent molecules, forming *hydronium ions* (H_3O+).

An acid may also be defined as a substance that serves as a *proton donor*—that is, it readily gives up a proton to another substance. However, acids are most broadly defined as compounds that are *electron pair acceptors.* This definition describes all acids, including those that have no hydrogen that they can release and that cannot serve as proton donors. The acid accepts a pair of electrons from another atom or molecule. In such cases, the acid and the electron pair donor form a new molecule in which they share the electrons.

The strength of an acid depends on the degree to which the acid *dissociates* (breaks up) in solution to form hydrogen ions. For example, in water solution, every molecule of hydrogen chloride (HCl) releases a hydrogen ion to form hydrochloric acid. Hydrochloric acid is therefore considered a strong acid. *Acetic acid* (CH_3COOH), which is found in vinegar, forms only a few hydrogen ions in solution. It is a weak acid.

Inorganic acids, in general, do not contain carbon atoms. Many inorganic acids are strong acids. They are used in the production of other chemicals, explosives, fertilizers, metals, paints, plastics, and synthetic fibers, and in the refining of petroleum. *Sulfuric acid* (H_2SO_4), a strong inorganic acid, is commonly used as the fluid in automobile batteries. Other important inorganic acids are hydrochloric acid and *nitric acid* (HNO_3).

Organic acids contain carbon atoms. They are used in beverages, cosmetics, detergents, foods, drugs, plastics, and soaps. Common organic acids include *citric acid* ($C_6H_8O_7$), which is found in citrus fruits; *ascorbic acid* ($C_6H_8O_6$), or vitamin C; and *acetylsalicylic acid* ($C_9H_8O_4$), or aspirin. *Amino acids,* which contain nitrogen, are also organic acids. Amino acids are the building blocks of proteins, and some of them are necessary for human life. Emily Jane Rose

Acid rain is a term for rain, snow, sleet, or other wet precipitation that is polluted by such acids as sulfuric acid and nitric acid. Acid rain harms thousands of lakes, rivers, and streams worldwide, killing fish and other wildlife. It also damages buildings, bridges, and statues. In high concentrations, it can harm forests and soil.

Acid rain forms when water vapor in the air reacts with certain chemical compounds. These compounds, including sulfur dioxide and nitrogen oxides, come largely from the burning of coal, gasoline, and oil. Most automobiles, factories, and power plants burn such fuels for energy. Regions affected by acid rain include large parts of eastern North America, Scandinavia and central Europe, and parts of Asia. Since about the 1950's, the problem has increased in rural areas. This has occurred because the use of taller smokestacks in urban areas has enabled the winds to transport pollutants farther from their sources.

Scientists and engineers have developed ways to reduce the acidity of rain. For example, several kinds of devices remove sulfur and nitrogen compounds from fuels or industrial emissions before they reach the atmosphere. Adding lime to lakes and rivers and their drainage areas temporarily neutralizes their acidity. But the neutralization may have harmful side effects.

In 1990, the United States Congress amended the Clean Air Act of 1970 to reduce acid rain in the United States and Canada. The amendments tightened emissions standards and required fuels that burn more cleanly. In 1999, the World Health Organization published air quality guidelines designed to reduce worldwide production of pollutants that result in acid rain and other environmental problems. Marian R. Chertow

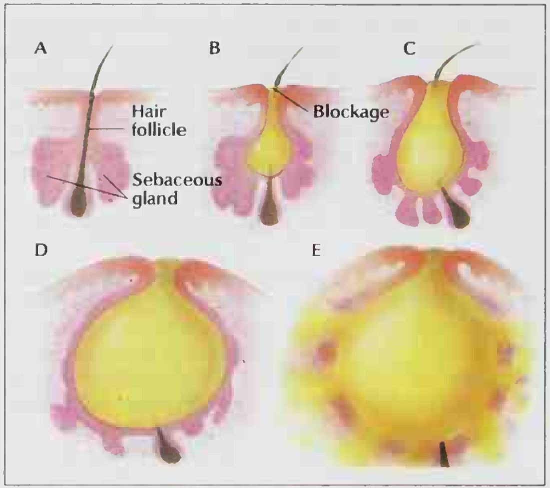
Acidosis, *as uh DOH sihs,* is a condition in which the body fluids tend to have a higher acid content than normal. The body has a variety of ways to compensate for mild acidosis. But prolonged acidosis can produce weakness, headache, and heavy or rapid breathing. Severe acidosis may lead to *acidemia*—a build-up of acids in the blood. Acidemia can result in coma and death.



Acidosis itself is not a disease, but it may warn of the presence of a disease. It arises from disorders that cause the body to accumulate excess acid or to lose too much alkali. Most of these disorders are *respiratory failures* or *metabolic failures.* Respiratory acidosis results from such disturbances as severe lung disease, blockage of the upper air passages, and chest injury. Metabolic failures involve malfunctioning of the process by which the body changes food into energy and tissue. Metabolic acidosis arises from kidney failure, diabetes, poisoning, and severe diarrhea. Treatment usually consists of correcting the underlying problem and administering sodium bicarbonate or another alkaline substance through a vein. Edward E. Morse

ACLU. See **American Civil Liberties Union.**

Acne is a skin disorder that occurs most commonly among teen-agers. It consists of various kinds of blemishes, mainly on the face, upper chest, and back. A few blemishes are normal, but severe acne may result in permanent scarring. Some teen-agers find severe acne so distressing that they develop emotional problems.

In most cases, acne appears during early adolescence —at about the age of 13, when a child starts to develop physically into an adult. This development is controlled by chemical substances called *hormones.* One kind of hormone stimulates the oil glands in the skin. These glands, which are called *sebaceous glands,* grow larger and produce more oil. Each sebaceous gland empties into a *hair follicle,* a cylinderlike structure that surrounds a hair. Normally, the oil empties out of the folli-

WORLD BOOK illustrations by Charles Wellek

The development of an acne pimple is illustrated above. Figure A shows a normal hair follicle and sebaceous gland. In figure B, a blockage prevents the flow of oil out of the hair follicle. Bacteria breed in the backed-up oil. In figures C and D, the follicle swells with pus. The walls of the follicle eventually burst, and the pus drains away, as shown in figure E.

cle through a pore that opens onto the surface of the skin.

Sometimes the pores become plugged and oil accumulates under the plugs. A plugged pore forms a blemish called a *blackhead* or *whitehead.* The black color of a blackhead comes from a normal skin pigment that darkens when exposed to air. A whitehead develops if a pore is so clogged that no air can enter.

Small, pus-filled bumps called *pimples,* or tender red lumps called *cysts,* may also develop. In pimples and cysts, a type of bacteria called *Propionibacterium acnes* breeds in the follicles, sebaceous glands, and backed-up oil, producing inflammation that causes the redness and pus. Cysts may leave permanent scars, but pimples usually do not scar unless squeezed or picked.

A poor diet, worry, and various bad habits are often blamed for acne, but they have little to do with the disorder. A balanced diet, enough sleep and exercise, and regular washing are good for the complexion and general health but cannot prevent or cure acne. Mild acne can be treated with nonprescription lotions that contain benzoyl peroxide or other medications. Heavy makeup makes acne worse and should not be used.

Severe acne should be treated by a physician. An antibiotic called *tetracycline* may be prescribed. This drug blocks the growth and reproduction of *Propionibacterium acnes* bacteria. Medications containing vitamin A acid may be applied to the skin to help prevent new blemishes. Other treatment used by doctors includes removing blackheads, freezing the skin with dry ice or liquid nitrogen to make it peel, and using a sun lamp. A drug called *isotretinoin* may be used to treat severe acne. But this drug, which has the trade name Accutane, can cause birth defects. It should not be used by women who are pregnant or who may become pregnant while undergoing treatment. David T. Woodley

Aconite, *AK uh nyt,* is the name of a group of plants that thrive in cool, northern regions. They are *perennials,* which means they can live for more than two years. There are more than 100 species. Most of them grow in Asia. Aconite flowers bloom in spring and summer and vary in color from purple-blue to yellow and white.

Aconites may grow from 1 to 6 feet (30 to 180 centimeters) high. The upper parts of their flowers resemble hoods or helmets. The roots, seeds, and leaves of some aconites are poisonous. A species of aconite called the *helmet flower* produces a poisonous drug also called *aconite.* This drug contains a powerful chemical, *aconitine,* which was once used extensively as a medicine.

Jerry M. Baskin

WORLD BOOK illustration by Christabel King

The helmet flower is an aconite that has purplish flowers. The plant produces a poisonous drug also called *aconite.*

Scientific classification. Aconites belong to the crowfoot family, Ranunculaceae. The scientific name for the helmet flower is *Aconitum Napellus.*

Acorn is the nut produced by any of the various kinds of oak trees. Acorns are sometimes used to feed hogs. Many wild birds and mammals, including quail, deer, and squirrels, eat acorns. Many kinds of acorns are bitter. American Indians crushed acorns and soaked them in water to remove the bitterness. American pioneers ate acorns when food was scarce. See also **Oak.**

Richard A. Jaynes

Acoustics, *uh KOOS tihks,* is the study of how sounds are created, transmitted, and received. The word *acoustics* also refers to the quality of sound as heard or transmitted in a room or concert hall. Two of the major fields in the study of acoustics are *architectural acoustics* and *environmental acoustics.*

Architectural acoustics deals with making rooms and buildings quiet and providing good conditions for listening to speech and music. It plays an important role in the planning and construction of auditoriums, churches, halls, libraries, and music rooms.

The acoustical quality of a room is affected by various factors. These include (1) the size and shape of the room; (2) the ability of the ceiling, walls, and floor to keep out unwanted sound; and (3) the use of furnishings made of sound-absorbing materials.

Another factor in the acoustical quality of a room is the way the room reflects sound. Sounds made by a speaker or a musical instrument bounce back and forth against the ceiling, walls, floor, and other surfaces. These reflections of a sound make up its *reverberation.* The *reverberation time* of a room is the time in which a sound dies away to one-millionth of its original energy. Reverberations should last about one second in an auditorium designed for speech, and about two seconds in a music hall. But no single strong reflection should arrive at a listener's ear later than about $\frac{1}{20}$ of a second after the arrival of the direct sound from a speaker or instrument. Otherwise, the listener hears the strong reflection as a disturbing echo of the original sound.

Furnishings made of sound-absorbing materials control reflection in a room. These include acoustical tiles, carpets, drapes, and upholstered furniture.

Environmental acoustics involves the control of noise pollution, a widespread problem in many residential areas. Major sources of environmental noise include automobiles and other motor vehicles, aircraft, industrial plants, and heavy construction equipment.

Noise pollution can be controlled in three ways: (1) by quieting the source of the noise, (2) by blocking the passage of noise from one place to another, and (3) by absorbing noise energy. For example, mufflers quiet the noise of automobile engines, heavy walls that have no cracks or pores block noise, and furnishings made of acoustical materials absorb noise.

Frequent exposure to intense noise can damage a person's hearing temporarily or permanently. The intensity of noise is measured in units called *decibels.* Federal laws require industries to reduce factory noise to 90 decibels or lower or to order workers to use protective earplugs or earmuffs.

Other areas of acoustics include (1) physiological acoustics—the way we hear sounds; (2) psychological acoustics—the way we interpret sounds; (3) musical acoustics—the way instruments and voices produce sounds; and (4) speech communication—the way we produce and hear speech. Acoustics also includes the study of sound waves that we cannot hear. For example, *infrasound* is too low in frequency for the human ear, and *ultrasound* is too high in frequency. Sound waves within the earth and underwater also fall outside the range of human hearing and form fields of study.

James D. Chalupnik

Acronym. See **Abbreviation.**

Acropolis, *uh KRAHP uh lihs,* was the religious and military center of a city-state in ancient Greece. The Greeks usually fortified a hill, called an acropolis, within or near the city for defense. The acropolis was often the first place to be inhabited. During the height of the Mycenaean era (1400 to 1200 B.C.), the palace of a local king was usually built on a hill. The palace also served as a military fort and a place of refuge for the townspeople in emergencies. The most important temples were also built on the hill, including the local shrines of the gods.

The most famous acropolis was in Athens. The Athenian Acropolis was a rocky hilltop, originally the site of the local armory and royal palace. The Persians demolished many old buildings on the Acropolis during a destructive invasion in 480 B.C. The Athenians then built a magnificent new group of temples. From 447 to 432 B.C., the Athenians built the Parthenon, dedicated to the virgin goddess Athena, the patron of the city (see **Parthenon**). The Erechtheum, built to honor the legendary founders of the city, was constructed from 421 to about 406 B.C. The Temple of Athena Nike, built about 425 B.C., honored Athena as the goddess of victory. Two theaters and several minor sanctuaries also occupied the slopes of the hilltop. On sacred holidays, a procession made its way up the slopes of the Acropolis and passed through the Propylaea, a large roofed gateway, to various temples. William J. Hennessey

Art Resource

An acropolis served as the religious and military center of an ancient Greek city-state. The Acropolis in Athens includes the Parthenon, *upper right,* and ruins of other ancient temples.

For pictures of the Acropolis in Athens, see **Athens; Greece.**

Acrylic, *uh KRIHL ihk,* is any one of a group of synthetic products made primarily from petroleum. Acrylics are

manufactured as fibers or plastics or as substances called *resins* (see **Resin, Synthetic**). Common acrylics include Acrilan, Lucite, Orlon, and Plexiglas.

Acrylic fibers are woven or knitted into durable fabrics of various textures. These fabrics dry rapidly and resist fading, wrinkling, and mildew. They are used to make blankets, carpets, sweaters, and many other products.

Acrylic plastics are tough materials that resist weathering, sharp blows, and corrosion. Acrylic plastics are often used as substitutes for glass in such products as aircraft windows, television screens, automobile tail lights, and lighting fixtures. They are less breakable than glass but are more easily scratched.

Liquid acrylic resins are used to make paints and synthetic waxes. Acrylic paints dry quickly and provide strong protection against the weather. They are widely used as house paints and in coatings for automobiles. High-gloss acrylic waxes are spread as protective coatings on floors and automobiles.

Acrylic adhesives and sealants are made from soft, elastic acrylic resins. Acrylic adhesives are used in such products as prepasted wallpaper and tapes. Acrylic sealants are used to seal cracks and joints in buildings.

Act of ... Laws that begin *Act of* or *Act for* appear under their key words, as in **Union, Act of.**

Actaeon. See **Artemis.**

ACTH is an abbreviation of the chemical substance *a*dreno*c*ortico*t*ropic *h*ormone. This hormone is produced, stored, and released into the blood by the *pituitary gland,* a pea-sized organ that lies at the base of the brain. ACTH is necessary for the normal growth and function of the *adrenal glands,* two organs located on top of the kidneys. ACTH stimulates the adrenal glands to secrete various hormones, including a group called *glucocorticoids.* Glucocorticoids regulate the use of digested food and help the body adjust to stress.

Normally, the pituitary gland releases high levels of ACTH in the morning and low levels at night. Physical or mental stress or disruption of a person's normal sleeping habits can change this pattern. Disturbances in the production or release of ACTH can cause severe illness.

Physicians use ACTH in the treatment of certain illnesses and of inflammation. ACTH used for medical purposes is obtained either synthetically or from the pituitary glands of animals. Charlotte H. Greene

Acting. See **Motion picture** (Assembling the cast; Holding rehearsals); **Television; Theater** (The performers).

Actinide. See **Rare earth; Element, Chemical** (Periodic table of the elements).

Actinium, *ak TIHN ee uhm,* a chemical element, is an extremely rare, silvery-white, radioactive metal that glows in the dark. It is formed naturally by the decay of uranium 235. Actinium also can be artificially prepared from radium treated with neutrons in a nuclear reactor. It is a difficult element to study because it can be produced only in very small quantities and because it decays into products that give off radiation.

Actinium has the chemical symbol Ac. Its atomic number is 89. Its most stable isotope has an atomic weight of 227 and a half-life of 22 years. Actinium melts at 817 °C and boils at 2470 °C. Most simple actinium compounds, such as the oxides, hydrides, and halides, contain the positively charged actinium ion, Ac^{3+}. André Debierne, a French scientist, discovered actinium in 1899.

S. C. Cummings

Actinomycosis, *AK tuh nuh my KOH sihs,* is a rare, infectious disease that affects human beings. It is characterized by the formation of painful abscesses in the mouth, lungs, or digestive organs. These abscesses grow larger as the disease progresses, often over a period of months. In severe cases, the abscesses may bore through bone and muscle to the skin, where they break open and leak large amounts of pus. Actinomycosis can destroy a person's jaw or lungs. It can also block the passage of food through the digestive system. It occurs in cattle and other animals as a disease called *lumpy jaw.* This name refers to the large abscesses that grow on the head and neck of the infected animal.

Actinomycosis is caused by any of several members of a group of bacteria called *actinomyces.* These bacteria are *anaerobes*—that is, they cannot survive in the presence of large amounts of oxygen. Actinomyces normally live harmlessly in the small spaces between the teeth and gums. They cause infection only when they can multiply freely in places where oxygen cannot reach them. The three most common sites of infection are decayed teeth, the lungs, and the intestines. Doctors use penicillin to treat actinomycosis. John R. Graybill

ACTION was a federal agency that directed the domestic volunteer programs of the United States government from 1971 to 1993. ACTION's programs included those that aided senior citizens, assisted low-income communities, and worked to prevent drug abuse. In 1993, most of these programs were transferred to the Corporation for National and Community Service. Some of them have been changed somewhat and renamed.

ACTION volunteers varied in age from 14 to more than 60 years old. They carried out programs in the 50 states, the District of Columbia, Puerto Rico, the Virgin Islands, and Guam.

ACTION originally included the Peace Corps, which coordinates U.S. volunteers who serve outside the country. In 1982, the Peace Corps became an independent agency (see **Peace Corps**).

Actium, *AK tee uhm* or *AK shee uhm,* **Battle of,** was a naval battle that settled the struggle for control of ancient Rome between co-rulers Gaius Octavian and Mark Antony. Octavian's forces won the battle, which took place in 31 B.C. off the coast of Actium, near present-day Preveza in western Greece.

Antony wanted to become the sole ruler of the vast Roman lands, which stretched across Europe. About 37 B.C., he married Cleopatra, the queen of Egypt, and began giving her Roman lands. War between Rome and Egypt broke out in 32 B.C. Antony and Cleopatra led 400 ships into the Battle of Actium. Marcus Agrippa, Octavian's chief military leader, commanded a fleet of equal size. Soon after the fighting began, Antony and Cleopatra apparently fled from the battle. Their navy then surrendered to Octavian's forces. In 30 B.C., Antony and Cleopatra committed suicide. In 27 B.C., Octavian became Emperor Augustus, the first emperor of the Roman Empire. William G. Sinnigen

See also **Agrippa, Marcus.**

Acton, *AK tuhn,* **Lord** (1834-1902), was one of the most respected historians of the 1800's. Many of his works focused on the history of freedom. Acton also planned the massive *Cambridge Modern History.* His statement that "Power tends to corrupt, and absolute power corrupts absolutely" has become a famous proverb.

Acton was a prominent liberal Roman Catholic. At Vatican Council I (1869-1870), he worked with bishops who opposed the church's adoption of the doctrine of *papal infallibility.* This doctrine states that the pope can commit no errors when he speaks as head of the church to define solemnly, in matters of faith and morals, what is to be accepted by all Roman Catholics.

John Emerich Edward Dalberg Acton was born on Jan. 10, 1834, in Naples, Italy. As a child, he moved with his family to the United Kingdom. In 1869, he became a baron. He was a professor of modern history at Cambridge University from 1895 until his death on June 19, 1902.

James C. Holland

Actor and actress. See the lists of biographies in the *Related articles* of Motion picture and Theater.

Acts of Supremacy. See Church of England.

Acts of the Apostles is the fifth book of the New Testament. It is a continuation of the Gospel of Luke. This Gospel and Acts are volumes one and two of a single work. According to Christian tradition, Acts was written by Saint Luke, a companion of Saint Paul. But many scholars doubt that this is true. Most scholars believe that Luke and Acts were written about A.D. 85.

Acts is the only record of the Christian church in the years just after the death of Jesus. It tells how followers of Jesus were His witnesses, first in Jerusalem and then in Judea and Samaria and finally "to the end of the earth" (Acts 1:8). Acts tells the story of the spread of the church mainly by narrating the career of Paul. In three missionary journeys, Paul evangelized what is now Turkey and Greece. After Paul was imprisoned and taken to Rome, he evangelized there. Terrance D. Callan

Acupuncture, *AK yuh puhngk chuhr,* is an ancient Chinese method of relieving pain and treating various diseases by inserting needles into specific places on the body. According to Chinese philosophy, acupuncture influences a life force that flows along 12 paired and 2 unpaired *meridians,* energy channels that run longitudinally in the body. Specialists called *acupuncturists* insert needles at points along these meridians or at painful points on the body. Insertion of the needles is said to restore balance between two principal forces of nature called *yin* and *yang.* Acupuncturists believe imbalance between these two forces causes disease and pain.

L. Steinmark, Custom Medical

Acupuncture relieves pain by the insertion of needles. This photo shows needles inserted near a person's ear.

Insertion of the needles produces a pinching feeling. This feeling quickly disappears and may be replaced by occasional tingling or a sense of numbness, heaviness, or soreness while the needles are in place.

Acupuncture is used alone or in combination with Western medicine or Chinese herbal preparations. It is most often used to relieve pain due to chronic illness and severe injury. Some common afflictions acupuncturists treat include headaches, sinusitis, chronic respiratory infections, digestive disturbances, and drug dependencies. Since the late 1950's, doctors in China have used acupuncture to relieve pain during major surgery. The patient is conscious and seems to feel little or no pain.

Researchers have shown that acupuncture increases the brain's production of natural painkillers called *endorphins.* These substances are morphinelike chemicals that influence the body's perception of pain (see **Endorphin**). Much of acupuncture's influence, however, is not understood.

Acupuncture is practiced widely in Asia and Europe, and it is gaining popularity and respect in the United States. Its practitioners include many medical doctors.

Joseph M. Helms

A.D. is the abbreviation for *anno Domini,* which is Latin for *in the year of our Lord.* In 532, the monk Dionysius Exiguus introduced a system of dating events, beginning with the year he believed Jesus Christ was born. In this system, the year of Christ's birth was A.D. 1, and the year before that was 1 B.C. (before Christ). Modern scholars believe Christ was actually born no later than 1 B.C. But people still determine dates using the original system.

Writers generally use *A.D.* and *B.C.* only to avoid confusion. When a writer mentions a year without using either abbreviation, readers should assume that the year was, or is, an "A.D." year.

Because there is no "year zero" in the dating system, it takes two steps to calculate an interval between a date in a "B.C." year and the same date in an "A.D." year. First, add the numbers representing the years. Then subtract 1. Thus, the interval between the end of 1 B.C. and the end of A.D. 1 was 1 year. The interval between the end of 2000 B.C. and the end of A.D. 2000 was 3,999 years.

An alternative system uses the same numbering method as that of Dionysius Exiguus, but does not refer specifically to Christ. In the alternative system, *C.E.,* which stands for *common era,* replaces A.D.; and *B.C.E.* (*before the common era*) replaces B.C. Michael Dine

Adam and Eve, according to the Bible, were the first man and woman created by God. The account of Adam and Eve is told in Genesis 2-3. According to Genesis, God created two human beings, later called Adam and Eve, and placed them in the Garden of Eden (see **Eden**). Adam and Eve lived in Eden, tending the garden of God. They were permitted to eat from any tree in the garden except from the tree of knowledge of good and evil. But a serpent persuaded Eve to eat fruit from this tree. Eve gave some to Adam, who also ate the fruit. Thus, they became mortal and God exiled them from Eden. Outside the garden, Adam had to work hard to make a living, and Eve also had to work and to bear many children.

The story of Adam and Eve begins a long Biblical narrative of human history. Their position at the beginning of the Bible makes them seem historical. But many Biblical scholars consider them as models who reveal the essential qualities of human existence. Their names are normally not proper names in Biblical Hebrew. They are general terms for *humanity* and *living being.*

According to one interpretation, the account of Adam and Eve focuses especially on those characteristics that define human nature as opposed to the nature of God and that of animals. Adam and Eve were made in God's image, and they gained wisdom, or knowledge of good and evil, which made them like God. But like animals, they had to die. Some people also believe the account emphasizes universal human fellowship by showing all humans as descendants of one couple. Carol L. Meyers

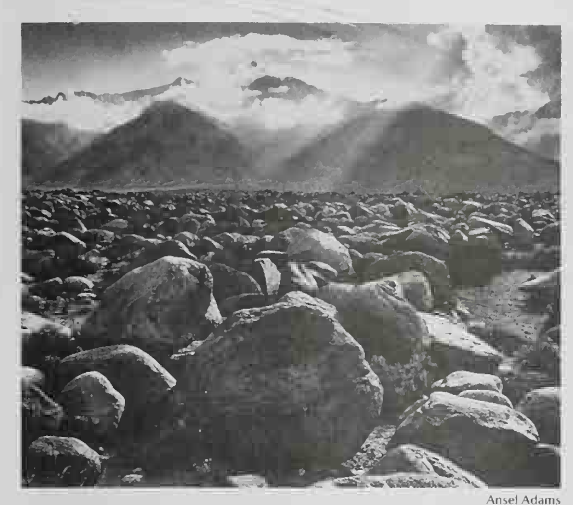
Adams, Abigail Smith (1744-1818), was the wife of John Adams, the second president of the United States. She also was the mother of John Quincy Adams, the sixth president. Abigail Adams is known for many letters containing her opinions of the society of her time.

Abigail Smith was born in Weymouth, Massachusetts. She and Adams were married in 1764. They had four children besides John Quincy Adams. She managed the family farm in Braintree (now Quincy), Massachusetts, while Adams served in the Continental Congress and as a diplomat in Europe during the 1770's and 1780's.

Abigail Adams supported women's rights and provided her daughter, Abigail, with a broad education. Writing to Adams in Philadelphia in 1776, she urged him to "remember the ladies" in the new nation's laws. She also opposed slavery.



During the Revolutionary War in America (1775-1783), Abigail Adams's letters to her husband contained valuable information about British troops and ships in the Boston area. In 1800, the Adamses became the first couple to live in the White House. Kathryn Kish Sklar

See also **Adams, John** (Adams' family; picture).

Adams, Ansel (1902-1984), was an American photographer known for his dramatic photographs of the West. He took large pictures of landscapes that include mountains, forests, and rivers. Adams's interest in preserving wilderness areas also led him to become active in the conservation movement.

Adams was a leading supporter of *straight photography,* a style featuring detailed, focused photos that portray subjects simply and directly. In 1932, he and six other photographers formed a group that promoted this style of photography.

In 1940, Adams helped found the Department of Photography at the Museum of Modern Art in New York City. In 1946, he established a photography department

Ansel Adams

Nature's majestic beauty is portrayed in Ansel Adams's photo *Mt. Williamson, Sierra Nevada, from Manzanar, California 1944.*

at the California School of Fine Arts (now the San Francisco Art Institute). This department was the first of its kind at a college in the United States. Adams also wrote a series of books on photography. He was born in San Francisco. Charles Hagen

Adams, Brooks (1848-1927), was an American historian and a critic of capitalism. He believed that commercial civilizations rise and fall in predictable cycles. First, masses of people draw together in large population centers and engage in commercial activities. Then, as their desire for wealth grows, greed replaces spiritual and creative values. Finally, the society crumbles. In *The Law of Civilization and Decay* (1895), Adams noted that as new population centers emerged in the West, centers of world trade shifted. They moved from Constantinople (now Istanbul, Turkey) to Venice, Italy, and eventually to London. Adams predicted in *America's Economic Supremacy* (1900) that Russia and the United States would become the leading world powers by 1950.

Adams was born in Quincy, Massachusetts. He was the son of U.S. diplomat Charles Francis Adams, brother of historian Henry Brooks Adams, and a grandson of President John Quincy Adams. Joseph Martin Hernon, Jr.

Adams, Charles Francis (1807-1886), was one of the most successful diplomats in United States history. He gained this reputation through his work as U.S. minister to Britain between 1861 and 1868. During these years, Adams helped keep Britain and France from recognizing the independence of the Confederacy during the American Civil War (1861-1865).

Adams was born in Boston. His father, John Quincy Adams, later became the sixth president of the United States. Charles spent his boyhood in Russia and Britain, where his father was U.S. minister. Charles graduated from Harvard University in 1825.

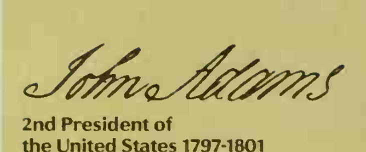
In the mid-1830's, Charles Adams became involved in the controversy over slavery in the United States. He served in the Massachusetts legislature from 1841 to 1845 and helped persuade fellow house members to take an open stand against slavery. He also edited the *Boston Daily Whig,* an antislavery party journal. Gradually, Adams became leader of the Conscience Whigs, an antislavery group. The group supported the Free Soil Party in 1848, which nominated Martin Van Buren for president and Adams for vice president. Zachary Taylor, the Whig candidate for president, won the election.

Adams devoted most of his time during the 1850's to editing the 10-volume *Works of John Adams.* He was elected to the U.S. House of Representatives from Massachusetts in 1858 and 1860. In 1861, President Abraham Lincoln appointed Adams minister to Britain. There Adams had to face strong sympathy for the Southern States in the Civil War. As minister, Adams struggled to prevent British recognition of Confederate independence and urged British officials not to equip Confederate ships. In 1871, President Ulysses S. Grant chose Adams to represent the United States in the settlement of claims involving the Confederate cruiser *Alabama* (see Alabama [ship]). Elliott Robert Barkan

Adams, Gerry (1948-), became the president of Sinn Féin *(shihn fayn),* an Irish nationalist political party, in 1983. Sinn Féin is the political wing of the Irish Republican Army (IRA), a group that has long sought to unite the country of Ireland with Northern Ireland, which is part of the United Kingdom.

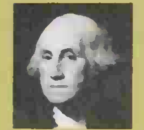
Adams defended the IRA's use of violence to achieve its goals. However, he also sought a peaceful settlement to the conflict. Adams participated in talks that led to a 1998 agreement committing all sides to resolve their differences by peaceful means. He also participated in hard-fought negotiations on implementation of the accord. See Northern Ireland (Recent developments).

Gerard Adams was born in Belfast, Northern Ireland. In 1964, while still in school, he joined Sinn Féin, where he worked for fair housing laws for Roman Catholics in Belfast. Adams was imprisoned by authorities in Northern Ireland during most of the 1970's because they suspected him of membership in the IRA. Adams denied being a member of the IRA. Paul E. Gallis



See also Irish Republican Army; Sinn Féin.

Adams, Henry Brooks (1838-1918), was an important American historian. His autobiography, *The Education of Henry Adams* (privately printed in 1907, published in 1918), won a Pulitzer Prize in 1919. In this book, Adams painted a vivid picture of the increasing sense of disconnectedness, terrifying diversity, and rapid change that many people began to experience in Western society during the 1800's.



Adams's greatest contribution to American history was the nine-volume *History of the United States* (1889-1891). In it, he made extensive use of historical documents to establish sure facts with little personal comment. He thus helped found the "scientific method" of history-writing that developed in the late 1800's. His *Mont-Saint-Michel and Chartres* (1913) established him as one of the best American writers of medieval history.

Adams was born in Boston, the son of American diplomat Charles Francis Adams. He was also the grandson of U.S. President John Quincy Adams and the great-grandson of President John Adams. Henry Adams graduated from Harvard University in 1858 and taught history there from 1870 to 1877. He edited the *North American Review* from 1870 to 1876. Adams also wrote two novels—*Democracy* (1880) and *Esther* (1884).

Thomas Jefferson
Vice president
1797-1801

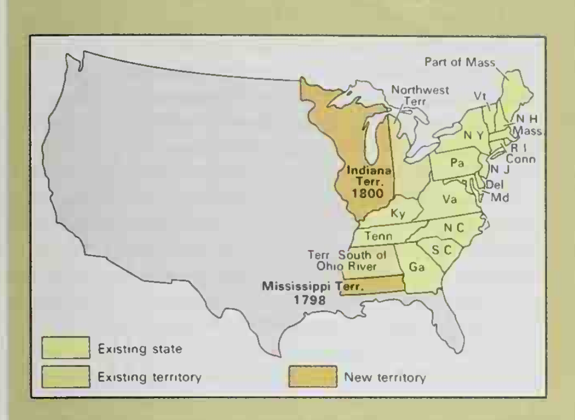
Adams, John (1735-1826), guided the young United States through some of its most serious troubles. He served under George Washington as the nation's first vice president and followed him as the second president. The United States government moved from Philadelphia to Washington, D.C., during Adams's administration, and he became the first President to live in the White House. Adams was the first chief executive whose son also served as president. The second father and son to be elected president were George Herbert Walker Bush, who held office from 1989 to 1993, and George Walker Bush, who was elected in 2000.

Adams played a leading role in the adoption of the Declaration of Independence, and was a signer of the historic document. He had spoken out boldly for separation from Britain at a time when most colonial leaders still hoped to settle their differences with the British. As president, Adams fought a split in his own party over his determination to avoid war with France. He kept the peace, but in the process he lost a second term as president. He was succeeded by Thomas Jefferson.

Adams seldom achieved popularity during his long political career. Adams was anything but a cold man, and those who knew him well, loved him. But his bluntness, impatience, and vanity made more enemies than friends. On the great decisions of his public career, history has proved him right and his opponents wrong. But his clumsiness in human relations often caused him to be misunderstood. Few people knew about another part of Adams's personality. His diary and personal letters show his genial, affectionate, and often playful nature.

During Adams's term, the United States took its first steps toward industrialization. The first woolen mills began operating in Massachusetts, and Congress established the Department of the Navy and the Marine Corps. Americans enjoyed such songs as "The Wearing of the Green" and "The Blue Bells of Scotland." People read and admired *The Life and Memorable Actions of George Washington* by Mason Locke Weems. On the frontier, Johnny Appleseed began wandering through Ohio and Indiana, planting apple seeds and teaching the Bible.

Early life



Childhood. John Adams was born in Braintree (now Quincy), Massachusetts, on Oct. 30, 1735. (The date was October 19 by the calendar then in use.) His father, John Adams, was a farmer, a deacon of the First Parish of Braintree, and a militia officer. His mother, Susanna Boylston Adams, came from a leading family of Brookline and Boston merchants and physicians.

The Adams farm lay at the foot of Penn's Hill. The city of Quincy has preserved as a memorial the house in which John Adams was born. The house stands close to the place where his great-great-grandfather, Henry Adams, settled before 1640. Henry Adams had sailed from Somerset, England, along with thousands of other Puritans, to escape the religious persecution found in his homeland.

Young John helped with the chores on the farm. He studied hard in the village school, but did not particularly enjoy books.

Education. Adams graduated from Harvard College in 1755, ranking 14th in a class of 24. In those days, the rank of a student indicated social position, not scholarship, and Adams was one of the best scholars in his class.

After teaching school for a short time, Adams studied law in the office of James Putnam in Worcester, Massachusetts. He began to practice law in Braintree in 1758. Ten years later he moved to Boston, where he became a leading attorney of the Massachusetts colony.

Two new territories were organized during Adams' presidency—the Mississippi Territory in 1798 and the Indiana Territory in 1800. No new states entered the Union.

The world of President John Adams

The rebirth of the United States Navy was symbolized by the launching of the frigate *United States* in 1797. Two other ships launched that year, the *Constitution* and the *Constellation,* made up the core of the nation's first naval force since the Revolutionary War. Congress established a separate Department of the Navy in 1798.
The United States Marine Corps was established by Congress in 1798 as a separate military service. The nation's first marine corps had been dissolved after the Revolutionary War.
The first organized strike in the United States took place in 1799. A group of Philadelphia shoemakers refused to work for nine days, until their demands for higher wages were met.
Napoleon became First Consul of France in 1799 and began to rule as a dictator.
The Library of Congress was established in 1800. Congress appropriated $5,000 to buy books and to furnish a room in the Capitol to house the library.
The federal government moved to Washington, D.C., from Philadelphia in June 1800. Congress convened in the new capital city for the first time in November of that year.
France secretly reacquired Louisiana from Spain in 1800. The United States did not learn of the transaction until the following year.

WORLD BOOK map

Adams' family. In 1764, Adams married Abigail Smith (Nov. 22, 1744-Oct. 28, 1818), the daughter of a minister in Weymouth, Mass. Their eldest son, John Quincy Adams, became the sixth President the year before his father died.

Like most women of her time, Abigail Adams had received little formal schooling. But she read widely, and became one of the best-informed women of the day. She wrote delightful letters to Adams during his absences from home. John Quincy Adams' son, Charles Francis, published many of these letters in 1840. Mrs. Adams was a lively observer of people and events, and her letters provide colorful pictures of colonial life.

The Adams' eldest child, Abigail, became the wife of Colonel William Stephens Smith, the secretary to the United States legation in London. The third child, Susanna, died in infancy. The fourth child, Charles, died while his father was President. Thomas, the youngest child, became a lawyer and a judge.

Doris S Oberg, Quincy Historical Society

John Adams' birthplace stands in Quincy (then Braintree), Mass. Farmland surrounded the house at the time of Adams' birth. The house is now preserved as a national historic site.

Political and public career

In New England. Adams took a leading part in opposing British colonial policies in America. The year 1765, when the British Parliament passed the Stamp Act, was a turning point in his life. This law taxed newspapers, legal papers, and other items. It hit Adams hard as a lawyer. He wrote: "This tax was set on foot for my ruin as well as that of Americans in general."

Adams wrote resolutions against the tax which were adopted by the Braintree town meeting. More than 40 other Massachusetts towns adopted these resolutions. The Boston town meeting appointed a committee to

Important dates in Adams' life

1735 (Oct. 30) Born in Braintree (now Quincy), Mass.
1764 (Oct. 25) Married Abigail Smith.
1774 Chosen a delegate to the First Continental Congress.
1777 Elected commissioner to France to negotiate a treaty of alliance.
1780-1782 Obtained recognition of American independence from the Netherlands.
1782-1783 Served on the commission that negotiated peace with Great Britain.
1785 Appointed minister to Great Britain.
1789 Elected Vice President of the United States.
1792 Reelected Vice President.
1796 Elected President of the United States.
1826 (July 4) Died in Quincy.

Oil painting on canvas (1785) by Mather Brown, New York State Historical Association, Cooperstown, N.Y.

Abigail Smith Adams was an intelligent, well-read woman, and a keen observer of colonial life. She and her husband carried on a lively correspondence when he was away from home.

present a petition against the tax to the British governor, and Adams served as one of the three members. He argued that the tax was illegal because the people had not consented to it. This amounted to saying that Parliament could not tax the colonies at all. Britain repealed the Stamp Act in 1766. See **Stamp Act**.

Adams rejoiced at every expression of popular opposition to the British. But the treatment of British soldiers who had taken part in the Boston Massacre distressed him (see **Boston Massacre**). His sense of justice led him to defend Captain Thomas Preston and the British soldiers charged with manslaughter. He felt that the soldiers should be freed, because they had only obeyed orders. Adams feared his viewpoint would cost him popularity. Instead, his prestige rose. In 1770, the people of Boston chose him as one of their representatives in the colonial legislature. There, with the help of his cousin, Samuel Adams, he led the fight against British colonial policies.

The British tax on tea enraged Adams and most of his fellow colonists. When a band of patriots dumped large quantities of tea into Boston Harbor on Dec. 16, 1773, Adams called this act "the most magnificent movement of all." See **Boston Tea Party**.

National politics. In 1774, the British government passed several laws that became known as the Intolerable Acts (see **Intolerable Acts**). Several of the colonies promptly called for representatives from each colony to meet in Philadelphia. Adams was one of the four Massachusetts delegates at this meeting, later called the First Continental Congress. He and a few other men wanted to seek independence from Britain, but he knew it was too early to propose such drastic action.

Adams' influence had grown by the time the Second Continental Congress met in 1775. He began to insist that the colonies should be independent, and opposed all halfway measures. He persuaded Congress to organize the 16,000 militiamen of New England as the Continental Army. He also helped bring about the appointment of George Washington as commander in chief.

Beginning in 1776, Adams served as chairman of the Continental Board of War and Ordnance. He also worked on a committee appointed to draft a plan for treaties with European powers, especially with France. Adams later wrote: "I was incessantly employed through the whole fall, winter, and spring of 1775 and 1776, in Congress during their sittings, and on committees in the mornings and evenings, and unquestionably did more business than any other member of the house."

On June 7, 1776, Richard Henry Lee of Virginia presented a resolution to Congress declaring that "these United Colonies are, and of right ought to be, free and independent States." Adams seconded the resolution. Congress chose him a member of the committee to prepare a declaration of independence. Adams urged Thomas Jefferson to draft the document. Adams defended the Declaration in the stormy debate that followed in Congress. Jefferson later called Adams the "colossus of that debate."

Diplomat. Early in 1778, Congress sent Adams to Paris to help Benjamin Franklin and Arthur Lee strengthen American ties with France and other European nations. Adams arrived in Paris to find that treaties had already been signed with France. He noted that friction had developed among the American ministers, and wrote to Congress proposing that one person take charge of affairs in France. Congress chose Franklin, and Adams sailed home in 1779.

Upon his return to Massachusetts, the people of Braintree elected Adams to the convention that framed a state constitution. Adams wrote almost all the constitution, which won acclaim for its detailed bill of rights. Many other states adopted features of this Massachusetts Constitution of 1780.

During the Massachusetts constitutional convention, Congress appointed Adams to negotiate treaties of peace and trade with Great Britain. He sailed for Paris, and arrived in February 1780. The French, although allies of America, gave Adams no independence in doing his work. The proposed negotiations never got started. Adams then went to the Netherlands to promote diplomatic and commercial support for the American war effort. After two years of hard work, he obtained recognition of the United States as a sovereign power. He also obtained a loan of about $1,400,000 for the United States. Adams' mission to the Netherlands ranks as his greatest diplomatic achievement.

In the fall of 1782, Adams joined John Jay and Benjamin Franklin in Paris to meet British and French representatives and arrange a peace treaty. Adams and Jay distrusted the French foreign minister, Count de Vergennes. They feared he would sacrifice American interests to gain advantages for France and its ally, Spain. As a result, the Americans departed from their instructions and negotiated with the British without informing Vergennes of each step taken. Franklin smoothed over affairs with France after the British and Americans had agreed on peace terms.

British and American commissioners signed a preliminary peace treaty on Nov. 30, 1782. The document was signed again in Paris on Sept. 3, 1783, as the final peace treaty. Adams made sure that the United States kept fishing rights in North Atlantic waters. He also arranged provisions recommending amnesty for Americans who had remained loyal to the British. During the next two years, Adams negotiated another Dutch loan and served in Paris on a commission to negotiate trade treaties with many European governments. He was proud when the French called him "the Washington of negotiations."

In 1785, Congress named Adams the first U.S. minister to Great Britain. He hoped to negotiate treaties that would encourage trade with Britain. But the British proved to be uncordial, and made it clear that they would not relax their harsh trade policies. Adams eventually asked to be recalled, and returned home in 1788 after almost 10 years abroad.

Vice President. Adams had been home only a few months when he was named Vice President. At that time, every elector voted for two men for the presidency. The man who ran second became Vice President. Each of the 69 electors voted for George Washington, and 34 gave their second vote to Adams.

Adams later wrote that the vice presidency was "the most insignificant office that ever the invention of man contrived or his imagination conceived." But he presided over the Senate with dignity, and tried to avoid political arguments. When called upon to cast a tie-breaking vote in the Senate, he always sided with Washington, feeling that he should reflect the President's policies. Adams was reelected Vice President in 1792.

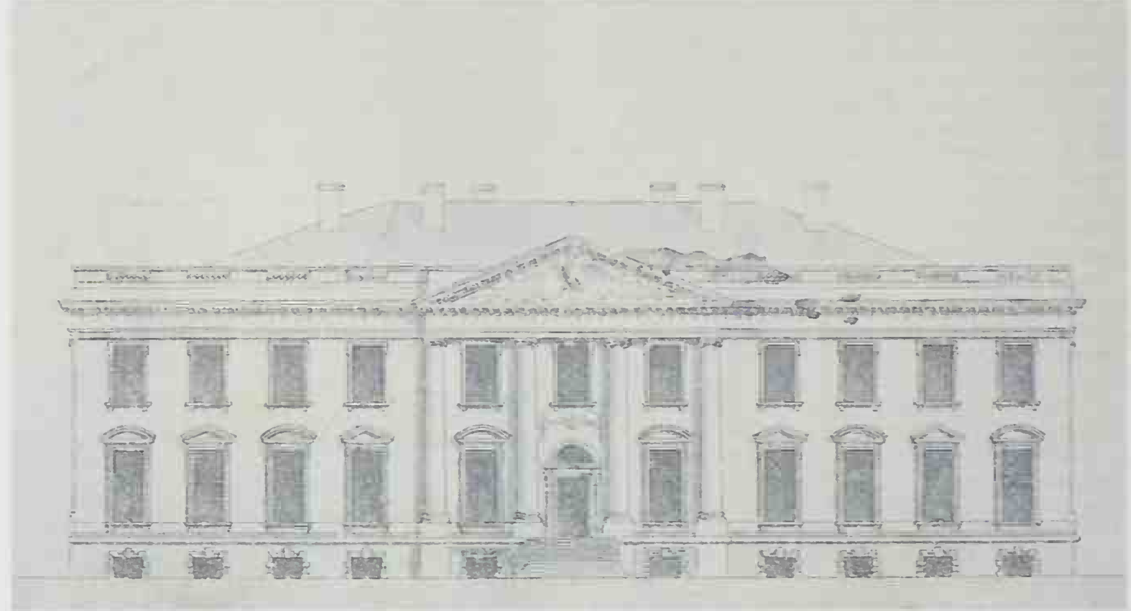
During his first term as Vice President, Adams wrote and published *Discourses on Davila,* a series of newspaper articles. Many readers thought these articles indicated that he had become much more conservative in his political views. Old friends, such as Thomas Jefferson, felt he had become too fond of kingly rule and too distrustful of popular government.

Two political groups began to form during Washington's second term. Adams and Alexander Hamilton led a group that favored a strong federal government. This group, known as the Federalists, supported Washington's policies. James Madison and Thomas Jefferson led the Democratic-Republicans (called Republicans at the time, though later to become the Democratic Party) in fighting for strong states' rights. Jefferson resigned as secretary of state in 1793 because he disapproved of the growing dominance of Hamilton in the Cabinet.

When Washington refused in 1796 to serve a third term, the two parties had become well defined. The Federalists supported Adams for the presidency, and the Democratic-Republicans nominated Jefferson. Adams received only three more votes than Jefferson did, and political opponents thus became President and Vice President.

Adams' Administration (1797-1801)

The Federalist split. During Adams' four years as President, the government faced many problems at home. Relations with European nations were also unsettled. To make his task more difficult, Adams could not count on the support of his party or his Cabinet. Disagreement over foreign policy split the Federalist Party into two groups. Adams led the more moderate of these groups. The other was led by Alexander Hamilton, who had left the Cabinet and returned to private life before Adams became President.



Difficulties with France. The French Revolution caused most of the problems that faced Adams. President Washington had insisted that neutrality was the best policy in case of a war in Europe. But, in the wars following the French Revolution, European warships attacked American ships. France and Great Britain claimed the right to seize American vessels. The United States was forced to protect itself, and the government launched several new warships, including the *Constitution* ("Old Ironsides").

The United States also became involved in the European wars on philosophical grounds. Jefferson believed

A View of the American Frigate, Constellation, Capturing the French National Frigate, L'Insurgente, engraving by an unknown artist (1800). New York Historical Society, New York City

Naval battles between U.S. and French ships occurred in spite of President Adams' efforts to keep the United States neutral during the European wars of the late 1700's.

Maryland Historical Society, Baltimore

John Adams was the first President to live in the White House. He and Mrs. Adams moved into the mansion in 1800, before it was completed, and suffered many inconveniences. The illustration above shows the original design for the White House by architect James Hoban.

that the French Revolution was a people's movement, like the Revolutionary War in America. His party sympathized with the French people, and wanted to aid them. But Hamilton led many Federalists in demanding a war against France. Adams was determined to keep the United States neutral, and deplored the policy of Hamilton and his followers. The split in the Federalist Party became irreparable.

One of Adams' first acts as President was to call a special session of Congress to consider ways of keeping peace. He sent ministers to France to work out a treaty. Three French diplomats offered to negotiate a pact if the United States would bribe Charles Maurice de Talleyrand-Périgord, the French foreign minister. This episode became known as the *XYZ Affair,* because the French diplomats were referred to by these initials instead of their names (see **XYZ Affair**). The Americans ended the negotiations late in 1797.

The XYZ Affair caused great anger in the United States. People rallied to the cry of "Millions for defense, but not one cent for tribute!" Congress began preparing for war with France. It established the Department of the Navy, ordered the construction of more warships, and summoned George Washington to command the Army.

*Has a separate biography in *World Book.*

Neither nation declared war, but American and French ships fought many battles.

Adams was still determined to keep peace. He again asked Talleyrand for a treaty. This time, Talleyrand was eager to negotiate, because he feared that the United States might join forces with Great Britain. Without consulting Congress, Adams sent a second commission to France. This act was the boldest of his career as President, and lost him support in his own party. But he believed that avoiding war was the most important achievement of his Administration.

The Alien and Sedition Acts. The Federalists faced bitter criticism because of their opposition to France. Most of the criticism came from American citizens, but some of the critics were French. In 1798, the Federalists passed laws designed to limit this criticism. Two *Alien Acts* gave the President authority to banish or imprison foreigners by a simple order. The *Sedition Act* made it a crime to criticize the government, the President, or Congress. Adams never used the Alien Acts, but a number of journalists who supported Jefferson were arrested for violation of the Sedition Act. See **Alien and Sedition Acts.**

These laws caused a storm of disapproval. Many people claimed they violated the guarantees of freedom of speech and of the press. Jefferson wrote the resolutions adopted by the Kentucky legislature declaring the Alien and Sedition Acts unconstitutional (see **Kentucky and Virginia Resolutions**). Historians agree that the acts were unwise.

Life in the White House. President Adams moved into the White House just a few months before the end of his Administration. The unfinished Executive Mansion stood in isolated splendor amid a dismal, swampy landscape. Abigail Adams wrote her sister: "As I expected to

find it a new country, with houses scattered over a space of 10 miles, and trees and stumps in plenty with a castle of a house—so I found it." Only half a dozen rooms of the White House were finished. Mrs. Adams had to dry the laundry in the East Room, because no drying yard had been provided.

The unfinished condition of the White House made it hard to carry on official social functions. But Adams and his wife struggled to overcome their difficulties. As the first residents of the White House, they felt they should set a social tone appropriate to the home of the President. Mrs. Adams admired the courtly entertainments of Martha Washington and tried to follow her example.

Election of 1800. Hamilton strongly criticized Adams for not fighting France. This argument influenced many Federalist voters. The Democratic-Republicans denounced Adams for the Alien and Sedition Acts, and for hostility toward France. The Democratic-Republican presidential candidates, Thomas Jefferson and Aaron Burr, received 73 electoral votes each. Adams received 65 electoral votes. The House of Representatives then chose Jefferson as President.

Late in 1800, the government had moved from Philadelphia to the new capital in Washington, D.C. Adams made appointments to government offices until his last day in office. One of his most important appointments was that of John Marshall as chief justice of the United States (see Marshall, John).

Later years

John Adams was nearly 66 years old when he left the White House. His defeat grieved him so much that he refused to stay in Washington for Jefferson's inauguration. He hurried off for his home in Quincy on the morning of March 4, 1801. Adams devoted himself to studying history, philosophy, and religion.

Quotations from John Adams

The following quotations come from some of John Adams's speeches and writings.

Liberty cannot be preserved without a general knowledge among the people ... but besides this, they have a right ... to that most dreaded and envied kind of knowledge, I mean of the characters and conduct of their rulers.

A Dissertation on the Canon and Feudal Law 1765

Facts are stubborn things; and whatever may be our wishes, our inclinations, or the dictates of our passions, they cannot alter the state of facts and evidence.

Argument in defense of the British soldiers in the Boston Massacre trials, December 1770

As the happiness of the people is the sole end of government, so the consent of the people is the only foundation of it.

Proclamation, 1774

Education makes a greater difference between man and man than nature has between man and brute.

Letter to Abigail Adams, Oct. 29, 1775

When annual elections end, there slavery begins.

Thoughts on Government, 1776

The fundamental article of my political creed is that despotism, or unlimited sovereignty, or absolute power, is the same in a majority of a popular assembly, an aristocratic council, an oligarchical junto, and a single emperor.

Letter to Thomas Jefferson, Nov. 13, 1815

Adams renewed his friendship with Thomas Jefferson. These two great Americans from North and South had met in Congress in 1775. Their friendship cooled steadily after about 1790, because they differed on the meaning of the French Revolution. But they forgot their political quarrels after retiring from public life.

By a remarkable coincidence, both men died on July 4, 1826. Adams's last words were: "Thomas Jefferson still survives." Adams died less than four months before his 91st birthday. He was buried in Quincy, Massachusetts.

Adams, John Quincy (1767-1848), was the first son of a president of the United States who also became president. The second father and son to be elected were George Herbert Walker Bush and George Walker Bush. Like his father, John Adams, he failed to win a second term. But soon afterward, he was elected to the U.S. House of Representatives. This pleased him more, he said, than his election as president.

Before entering the presidency, Adams held several important diplomatic posts. He took part in the negotiations that ended the War of 1812. As secretary of state, he helped develop the Monroe Doctrine. Quarrels within his party hampered Adams as president, and he made little progress with his ambitious legislative program. His years in the White House were perhaps the unhappiest period of Adams's life.

Adams was short and stout, and his shrill voice often broke when he became excited. Yet he spoke so well he was nicknamed "Old Man Eloquent." He was affectionate with close friends, but more reserved toward others. He once referred to himself as "an unsocial savage."

During Adams's administration, Noah Webster brought out his two-volume *American Dictionary of the English Language,* and James Fenimore Cooper published his famous novel *The Last of the Mohicans.* The American labor movement began in Philadelphia.

Early life

Childhood. John Quincy Adams was born on July 11, 1767, in the family home in Braintree (now Quincy), Massachusetts. He was the second child and eldest son of the second president of the United States. During the 1770's, his father was away much of the time serving in the Continental Congresses. John Quincy had to help his mother manage a large farm. In February 1778, Congress sent his father to France. John Quincy, although not yet 11, pleaded to go along on the dangerous voyage. His father proudly wrote in his diary: "Mr. Johnny's behavior gave me a satisfaction I cannot express. Fully sensible of our danger, he was constantly endeavoring to bear it with a manly patience, very attentive to me, and his thoughts constantly running in a serious vein."

Education. Adams attended schools in Paris, Amsterdam, and Leiden as his father moved from one diplomatic assignment to another. At 14, he went to St. Petersburg as private secretary to Francis Dana, the first American minister to Russia. The boy rejoined his father in 1783 and served as his private secretary.

When the elder Adams became minister to Britain in 1785, the boy returned home and entered Harvard College. He said later: "By remaining much longer in Europe I saw the danger of an alienation from my own country." His previous studies enabled him to join the junior class at Harvard. He graduated in 1787.

Lawyer and writer. Adams read law for three years and began his own practice in 1790. But he had few clients and soon turned to political journalism.

Important dates in Adams's life

1767 (July 11) Born in Braintree (now Quincy), Massachusetts.
1794 Became minister to the Netherlands.
1797 (July 26) Married Louisa Catherine Johnson.
1803 Elected to the United States Senate.
1809 Appointed minister to Russia.
1814-1815 Helped negotiate peace with the United Kingdom.
1815 Became minister to the United Kingdom.
1817 Appointed secretary of state.
1825 Elected president of the United States.
1830 Elected to the U.S. House of Representatives.
1848 (Feb. 23) Died in Washington, D.C.

The Erie Canal, completed in 1825, linked Lake Erie with the Hudson River. It enabled freight to be shipped between the Atlantic Ocean and the Great Lakes.

The world of President John Quincy Adams

The first women's labor union was organized in 1825. The union was formed by women working in the garment industry in New York City.

Czar Nicholas I of Russia crushed the Decembrist uprising, a revolt of discontented nobles, in 1825. As a result of wars fought during the late 1820's, Russia expanded its borders to include important territory on the Black Sea.

July 4, 1826, marked the 50th anniversary of the signing of the Declaration of Independence. In a remarkable coincidence, the deaths of two of the nation's Founding Fathers, Thomas Jefferson and John Adams, occurred that same day.

The Last of the Mohicans, one of James Fenimore Cooper's most popular works, was published in 1826.

The first overland expedition from Utah to California was led by trader and explorer Jedediah Smith in 1826. Smith crossed Indian territories, the Mojave Desert, and the High Sierras in search of trade routes to California and the Northwest.

The Creek Indians signed treaties in 1826 and 1827 that transferred land in western Georgia to the U.S. government.

Artist and naturalist John James Audubon published the first part of his masterpiece, *Birds of America,* in 1827. The work, eventually completed in 1838, consisted of 435 life-sized, color engravings of Audubon's water colors.

Noah Webster published *An American Dictionary of the English Language* in 1828. The two-volume work included about 12,000 words and 40,000 definitions that had never appeared in any other dictionary.

View on the Erie Canal, a water color (1832) by John William Hill; Stokes Collection, New York Public Library

In 1791, Thomas Paine published the first part of *Rights of Man.* Adams considered Paine's ideas too radical and replied with 11 articles that he signed with the name "Publicola." A second series, signed "Marcellus," defended President George Washington's policy of neutrality. A third series, signed "Columbus," attacked French minister Edmond Genêt, who wanted America to join France in a war against Britain.

Political and public career

Diplomat. In 1794, Washington appointed Adams minister to the Netherlands. The French invaded the country three days after Adams arrived and overthrew the Dutch Republic. On a special assignment in London, Adams met his future wife, Louisa Catherine Johnson (Feb. 12, 1775-May 15, 1852), the daughter of the American consul general.

In 1796, Washington appointed Adams minister to Portugal. Just before he left for Lisbon, his father was elected President. Both men felt it would be undesirable for the son to hold such a post during his father's Administration. But Washington urged that the younger Adams stay on, calling him "the most valuable public character now abroad." President Adams followed this recommendation and named his son minister to Prussia.

Adams' family. John Quincy married Miss Johnson in 1797, just before leaving for Berlin. He served there more than four years. Adams and his wife had four children. Their only daughter, Louisa Catherine, died in infancy. George Washington Adams, the eldest son, died in 1829, at the close of his father's presidency. John, who was named for his grandfather, died five years later. The youngest son, Charles Francis, served as minister to Great Britain during the Civil War.

U.S. senator. Thomas Jefferson became President in 1801. John Quincy Adams soon returned home, and was elected to the Massachusetts Senate in 1802. He soon displayed the independence that marked his entire career. Fisher Ames, the Federalist leader in Massachusetts, described him as "too unmanageable."

In 1803, the Federalists chose Adams to fill a vacant seat in the United States Senate. Although a Federalist, he often voted with the Democratic-Republicans. He broke with his party completely in 1807, when Congress passed the Embargo Act. The Federalists in New England wanted to trade with the British, but Adams supported the embargo, believing that it benefited the nation as a whole.

Doris S. Oberg, Quincy Historical Society

John Quincy Adams' birthplace stands in Quincy, Mass. His father, John Adams, was born in a nearly identical house next door. The two buildings are now historic sites.

Oil painting on canvas (1821) by Gilbert Stuart. © White House Historical Association (National Geographic Society)

Louisa Johnson Adams was born in London, the daughter of an American diplomat. She first came to the United States in 1801, four years after she married John Quincy Adams.

Federalist leaders in Massachusetts felt that Adams had betrayed them. They elected another man to his Senate seat several months before the 1808 elections. Adams resigned immediately and prepared for a career as professor of rhetoric and oratory at Harvard.

Again a diplomat. Adams intended to stay out of public life permanently. But in 1809, President James Madison persuaded him to accept an appointment as minister to Russia. From mid-1814 to early 1815, Adams served as one of the American commissioners who negotiated the Treaty of Ghent with the British, ending the War of 1812. The negotiations gained respect for the United States, as well as for Adams as a diplomat.

Madison next appointed Adams as minister to Great Britain, a post once held by his father. While in London, Adams began discussions that led to improved relations along the U.S.-Canadian border. Great Britain and the United States agreed to stop using forts and warships in the Great Lakes region, leaving the frontiers of the two countries unguarded and open.

Secretary of state. In 1817, President James Monroe called Adams home to serve as secretary of state. Adams made an agreement with Great Britain for joint occupation of the Oregon region. He negotiated a treaty that quieted Spanish claims to territory in the northwest and also acquired Florida. But his most important achievement as secretary of state was to help develop the Monroe Doctrine. Adams made the first declaration of this policy in July 1823, several months before Monroe formally announced it. He told the Russian minister that "the American continents are no longer subjects for any new European colonial establishments."

Austria, Prussia, and Russia had formed the Holy Alliance in 1815, after the fall of Napoleon. During and after the Napoleonic Wars, the countries of Central and South America had revolted against Spanish rule. When King Ferdinand VII regained the Spanish throne in 1823, many people feared that the Holy Alliance might help Spain reconquer its former colonies. British Foreign Minister George Canning asked the United States to join in a declaration against any such move. But Adams insisted that the United States should make its own policy. He declared that America must not "come in as a cockboat (small rowboat) in the wake of the British man-of-war." Monroe followed Adams' advice, and the Monroe Doctrine became a part of U.S. foreign policy. See **Monroe Doctrine**.

Election of 1824. Many Americans believed Adams should follow Monroe as President. Both Madison and Monroe became President after serving as secretary of state. Adams felt he also should be elected but did little to attract votes. Four Democratic-Republicans opposed him: John C. Calhoun, Henry Clay, William H. Crawford, and Andrew Jackson. Calhoun withdrew, and was elected Vice President. Jackson received 99 electoral votes; Adams, 84; Crawford, 41; and Clay, 37. For votes by states, see **Electoral College** (table). None had a majority, so the House of Representatives had to choose one of the first three men. Clay then threw his support to Adams, who was elected in February 1825.

Adams' Administration (1825-1829)

Democratic-Republican Party split. Even before the House elected Adams, followers of Jackson accused Adams of promising Clay a Cabinet post in return for his support. When Adams named Clay secretary of state, Jackson's powerful supporters in Congress charged that the two men had made a "corrupt bargain." This split the Democratic-Republican Party, and Adams' group became known as the National Republicans. Jackson's group fought Adams for the next four years.

Rebuff by Congress. Adams delivered his inaugural address in the Senate chamber of the unfinished Capitol. In this address, and in his first message to Congress, he recommended an ambitious program of national improvements. This program included the construction of highways, canals, weather stations, and a national university. He argued that if Congress did not use the powers of government for the benefit of all the people, it "would be treachery to the most sacred of trusts." But the majority in Congress disagreed. Adams' hopes for a partnership of government and science were not to be realized until after his lifetime.

The "tariff of abominations." By 1828, manufacturing had replaced farming as the chief activity in most New England states. These states favored high tariffs on imported goods. But high tariffs would make farmers in the South pay more for imported products. Southern leaders wanted a low tariff or free trade.

Jackson's supporters in Congress wrote a tariff bill that put high duties on manufactured goods. The bill also raised duties on raw materials so high that even New Englanders could be expected to oppose it. To everyone's surprise, enough New Englanders voted for the bill to pass it. The "tariff of abominations," as it became known, aroused bitter anger in the South.

Life in the White House. Adams threw all his energies into the presidency from the day he took office. Each day, he conferred with a steady procession of congressmen and department heads in his upstairs study in the White House. The President wrote in his diary: "I can scarcely conceive a more harassing, wearying, teasing condition of existence." He felt a lack of exercise, in spite

of daily walks. In warm weather, Adams liked to swim in the Potomac River.

Mrs. Adams suffered ill health during her husband's term as President, but she overcame her sickness to serve as White House hostess. She was responsible for a brilliant series of parties during the visit of the Marquis de Lafayette in 1825.

Election of 1828. Adams had never been popular, chiefly because of his aloof manner. He had not even tried to defend himself against the attacks of Jackson and his followers, feeling it was below the dignity of the President to engage in political debate. At the same time, Jackson gained great popularity. In the election of 1828, Jackson won a popular vote proportionately larger than any other presidential candidate received during the rest of the 1800's. He and his running mate, Vice President Calhoun, won 178 electoral votes. Adams and Secretary of the Treasury Richard Rush had 83.

Back to Congress

Election to the House. Adams again planned to retire, but the people of Quincy asked him to run for Congress in 1830. He defeated two other candidates by large majorities and wrote in his diary: "My election as President of the United States was not half so gratifying." He took his seat in the House of Representatives in 1831 and served for 17 years.

Adams served at times as chairman of the House Foreign Affairs Committee and of the Committee on Manufactures. But he remained independent of party politics. He fought President Jackson's opposition to the second Bank of the United States. He also opposed Jackson's policy of recognizing the independence of Texas. But Adams supported Jackson's foreign policy and stern resistance to nullification (see Nullification).

The Gag Rules. Adams' greatest public role may have occurred during debates about slavery. Abolitionists sent many petitions to Congress urging that slavery be abolished in the District of Columbia and in new territories. These petitions took much of the lawmakers' time. In 1836, the House adopted the first of a series of resolutions called the *Gag Rules* to keep the petitions from being read on the floor. Adams believed these rules violated the constitutional rights of free speech and petition. He was strongly criticized in the House for opposing the Gag Rules, but he finally succeeded in having them abolished in 1844.

Adams became the first congressman to assert the right of the government to free slaves during time of war. President Abraham Lincoln based the Emancipation Proclamation on Adams' arguments.

The Amistad Rebellion. In 1841, Adams again publically showed his opposition to slavery when he defended the Amistad rebels before the Supreme Court of the United States. The rebels were black Africans who had been captured and enslaved by whites. In 1839, they attacked their captors while on a ship called *La Amistad* in the Caribbean Sea. They killed two whites and took control of the vessel. They were later arrested in the United States for the killings and mutiny. Their case ended up in the Supreme Court. There, Adams strongly defended the rebels, arguing that every person has the right to freedom. The rebels were found not guilty. For more details, see Amistad Rebellion.

Death. On Feb. 21, 1848, he suffered a stroke at his House desk. Too ill to be moved from the building, he was carried to the Speaker's room. He died there two days later. Adams was buried in the churchyard of the First Unitarian Church in Quincy, Massachusetts. His wife died on May 15, 1852, and was buried at his side. Their remains were later moved to the church crypt.

Jack Shepherd

Quotations from John Quincy Adams

The following quotations come from some of John Quincy Adams' speeches and writings.

... may our country be always successful, but whether successful or otherwise, always right.

Letter to John Adams, Aug. 1, 1816

Internal improvements was at once my conscience and my treasure.

Letter to Henry Clay, Sept. 30, 1842

... above all, let us never forget, in the most fervent heat of our party conflicts, that there is a cause, embracing and transcending all others— ... the cause of our country.

Lecture given at Providence, Rhode Island, Nov. 25, 1842

Adams, Samuel (1722-1803), was an American patriot and politician who stirred opposition to British rule in the American Colonies. However, Adams attempted to make people work for their rights peacefully through committees and other meetings. He was willing to justify violent opposition to Britain only if all else failed. Adams was a signer of the Declaration of Independence.

Adams was born in Boston. He was the cousin of John Adams, who became the second president of the United States. Samuel graduated from Harvard College in 1740, received an M.A. degree from the college in 1743, and then entered private business. However, Adams failed in that career and by 1764 was deeply in debt.

The patriot. Adams became increasingly involved in politics. He belonged to several patriotic clubs and was a prominent figure in Boston town meetings. Adams opposed several laws passed by the British Parliament to raise revenue in the American Colonies. Those laws included the Sugar Act of 1764, the Stamp Act of 1765, and the Townshend Acts of 1767 (see **Stamp Act**). Adams served in the Massachusetts legislature from 1765 to 1774. As its clerk, he corresponded widely with other colonial leaders.

Parliament repealed the Stamp Act in 1766. In 1770, it canceled all the *duties* (import taxes) in the Townshend Acts except the tax on imported tea. Adams, however, believed American freedom was still in danger. In 1768, the British had sent soldiers to Boston. Adams thought the use of soldiers against civilians was a sign of tyranny. He served as a spokesman for the town of Boston after British troops killed several colonists in the Boston Massacre on March 5, 1770, and succeeded in getting the British troops sent elsewhere. In 1772, the Boston town meeting, spurred by Adams, set up a *committee of correspondence.* This committee published a declaration of colonial rights, which Adams had written, and sent it to other towns.

In 1773, Adams led Boston's resistance to the Tea Act, which gave a British company a monopoly on all tea exported to the colonies. The resistance reached its high point on the evening of Dec. 16, 1773, when a group of Bostonians dumped a cargo of British tea into the harbor (see **Boston Tea Party**).

Museum of Fine Arts, Boston
Samuel Adams

The British Parliament responded in 1774 by passing the so-called Intolerable Acts. Those laws included measures that closed the port of Boston, restricted town meetings, and made it easier for Britain to use troops against American civilians (see **Intolerable Acts**). Adams then urged all the American Colonies to boycott trade with Britain. Representatives of 12 colonies soon assembled in the First Continental Congress in 1774 (see **Continental Congress**). The Massachusetts legislature sent Adams and four others to represent it at the congress. In 1775, Adams began serving in the Second Continental Congress, where he pleaded for independence and a *confederation* (union) of the colonies. He narrowly escaped arrest by the British in Lexington while he was on his way to Philadelphia. Congress approved the Declaration of Independence in 1776.

In office. Adams served in the Continental Congress until 1781, when he returned to Boston. He at first opposed the newly written Constitution of the United States. In the end, however, he supported its *ratification* (approval) in Massachusetts. Adams served as governor of Massachusetts from 1793 to 1797. A statue of Adams represents the state in the U.S. Capitol. Pauline Maier

Adams, Samuel Hopkins (1871-1958), was an American journalist and author. Early in his career, Adams wrote newspaper and magazine articles that exposed dishonesty in business and government. His articles collected in *The Great American Fraud* (1906) dealt with patent medicine frauds and contributed to the passage of the first federal food and drug act in 1906.

About 1910, Adams began concentrating on fiction and wrote novels and short stories for both children and adults. Adams often used people and events from American history in his fiction. His most appealing historical works describe life along the Erie Canal in New York during the 1800's. His children's novel *Chingo Smith of the Erie Canal* (1958) is an example. Adams based his political novel *Revelry* (1926) on events in the administration of President Warren G. Harding. Adams also wrote several biographies and a number of mystery stories about an amateur detective called Average Jones. Adams's *Grandfather Stories* (1955) is a collection of essays. Adams was born in Dunkirk, New York. Bert Hitchcock

Adams, Scott (1957-), an American cartoonist, created the comic strip "Dilbert." Dilbert is an engineer who struggles daily with the often ridiculous policies of corporate management. Other characters include fellow employees Alice and Wally; Catbert, a cat who is the human resources director; and Dogbert and Ratbert, a dog and a rat who serve as consultants. Adams bases many of his cartoons on stories that readers send him about actual experiences at their jobs.

Adams was born in Windham, New York. He earned a graduate degree in business administration and held numerous jobs in technology and finance. "Dilbert" was first *syndicated*—that is, distributed to a large number of newspapers—in 1989. Several collections of Dilbert cartoons became best-selling books, including *The Dilbert Principle* (1996) and *Dogbert's Top Secret Management Handbook* (1996). Pamela J. Fehl

Adams, Sherman (1899-1986), served as chief of staff to United States President Dwight D. Eisenhower from 1953 to 1958. He resigned after Democratic and Republi-

can leaders criticized him for taking gifts from a Boston industrialist whose business affairs were under government investigation. Adams served as a Republican representative in Congress from 1945 to 1947, and as governor of New Hampshire from 1949 to 1953. He was born in East Dover, Vermont. Stephen E. Ambrose

Adam's apple. See Larynx.

Adamson, Joy (1910-1980), was a wildlife conservationist and author who won wide recognition for her observations on animal behavior in Africa. She is best known for her books *Born Free* (1960), *Living Free* (1961), and *Forever Free* (1962), in which she describes the life of the lioness Elsa. Elsa was raised in the Adamson household. She was then trained to survive in the wild by Adamson and her husband, George Adamson, a wildlife conservationist and game warden. The movie *Born Free* (1966), based on Joy Adamson's books, helped spread her message of concern for wildlife.

Joy-Friederike Victoria Gessner was born in Troppau, Silesia (now Opava, the Czech Republic). She went to Kenya at the age of 27, where she married George Adamson and lived for the rest of her life. They acquired Elsa after George had shot a lioness, Elsa's mother, in self-defense. They took Elsa and the lioness's two other orphaned cubs into their home. The couple trained Elsa to develop her natural hunting skills so that she could survive on her own. After her release into the wild, Elsa found a mate and raised three cubs.

The Adamsons were among the first conservationists to train a captive animal to establish its wild nature. They also worked to control *poaching,* the illegal killing of animals to obtain animal skins or the ivory of elephant tusks. Joy Adamson's books include *Joy Adamson's Africa* (1972) and an autobiography, *The Searching Spirit* (1978). Poachers shot her to death. George Adamson, who worked for Kenya's wildlife department, was fatally shot by poachers in 1989. G. J. Kenagy

Adaptation is a characteristic of an organism that makes it better able to survive and reproduce in its environment. No two organisms of the same species are exactly alike. Every trait, such as size, color, and personality, shows some variation. Additionally, in nature, organisms produce more offspring than can survive. The offspring most likely to survive and reproduce are those with adaptations best suited to the environment. Offspring with variations less suited to the environment do not compete as successfully for food, water, and other necessities. This process of competition, by which those best adapted are most likely to survive and reproduce is called *natural selection* (see Evolution).

Some forms of life are adapted to living in many different environments. For example, people live in all kinds of climates. Thus, human beings are *generalized*—that is, the human body has adaptations that enable people to live in widely different environments. But such organisms as mosquitoes and bamboo plants are more *specialized.* Because of their physical makeup, they can live only in a rather warm, wet climate.

Living things often die when they cannot adapt to a changing environment. Many kinds of plants and animals that once lived on the earth have become extinct. For example, millions of years ago, dinosaurs roamed the earth. But the environment in which they lived changed. The dinosaurs failed to adapt, and they died out (see **Dinosaur** [Why dinosaurs died out]).

The word *adaptation* also refers to the ability of living things to adjust to varying conditions in their environment. If people move to the mountains, their bodies adapt to the lower oxygen supply at high altitudes by making more oxygen-carrying red blood cells. A dog adapts to warm weather by shedding its hair. Adaptations that occur over a relatively short time, particularly because of changes in climate, are often called *acclimatizations.* Lawrence C. Wit

Secrets of Animal Survival. National Geographic Soc., 1983. Younger readers.

Addams, Charles (1912-1988), an American cartoonist, became famous for the morbid humor of his drawings. Addams enjoyed turning ordinary situations into ghoulish comedy. His cartoons featured ghosts, monsters, haunted houses, and cemeteries. Addams was best known for creating the comically grotesque characters called the Addams family. The family inspired a popular television series (1964-1966) and two motion pictures, *The Addams Family* (1991) and *Addams Family Values* (1993).

Charles Samuel Addams was born and raised in Westfield, New Jersey. He showed a fascination with the morbid at an early age, frequently visiting the local cemetery. His neighborhood had many Victorian houses like the spooky mansion he later drew for the Addams family. Addams achieved his greatest popularity as a cartoonist with *The New Yorker* magazine. He began publishing in *The New Yorker* in the 1930's and became one of the magazine's most celebrated cartoonists. Collections of Addams's cartoons have been published in several books. Pamela J. Fehl

Addams, Jane (1860-1935), was an American social worker and humanitarian. She and Ellen Gates Starr founded Hull House in Chicago in 1889 (see **Hull House**). Addams shared the 1931 Nobel Peace Prize with Nicholas Murray Butler. Visiting Europe in 1883 and in 1888, she became interested in Toynbee Hall, a settlement in London. On her return home, Addams created a more democratic kind of settlement house, sometimes called a "neighborhood center," among the immigrants in Chicago (see **Settlement house**). There she set up many programs, from day nurseries to college courses, designed for people of every nation and ethnic group.

Addams was not content with simple friendliness or with the programs she established. She believed strongly in the need for research into the causes of poverty and crime, in the importance of trained social workers, and in social action to press for reforms. She organized civic groups to bring pressure on legislatures and officials. Among the reforms with which she was closely associated were the first eight-hour law for working women, the first state child-labor law, housing reform, and the first juvenile court.

Addams wrote and lectured on a wide variety of social problems, including child labor, public health, unemployment relief, and social insurance. In 1909, she became the first woman president of the National Conference of Charities and Corrections, now the National Conference on Social Welfare.

University of Illinois at Chicago Library, Jane Addams Memorial Collection

Jane Addams

She led in the fight to give women the vote, and was a pacifist, serving as president of the Women's International League for Peace and Freedom from 1915 to 1929.

The width of her interest is reflected in her books, which include *Democracy and Social Ethics* (1902), *The Spirit of Youth and the City Streets* (1909), *Twenty Years at Hull-House* (1910), *Women at The Hague* (1915), *Newer Ideals of Peace* (1915), and *Peace and Bread in Time of War* (1922).

Addams was born of Quaker parents on Sept. 6, 1860, in Cedarville, Illinois. She graduated from Rockford College and began medical studies in Philadelphia. However, she was forced to give up her studies because of her health. Alan Keith-Lucas

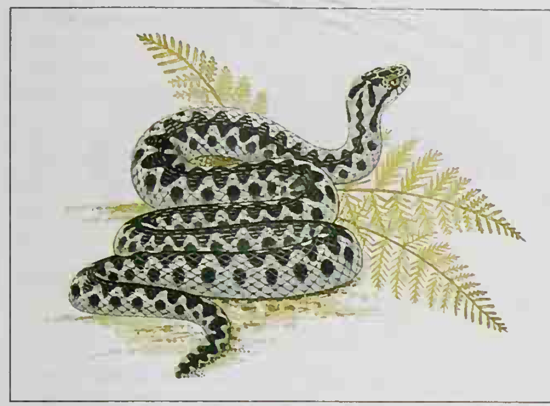
Addax, *AD aks,* is an antelope that lives in the deserts of northern Africa. The addax resembles its close relative, the oryx (see **Antelope** [Kinds of antelope; picture]).

The addax is well suited for desert life. It can withstand hot temperatures, go without water for long periods, and eat coarse desert plants. The addax stands about 3 ½ feet (107 centimeters) high at the shoulder. Its body and neck are grayish-brown in winter and sandy to almost white in summer. There is a patch of chestnut-colored hair on the forehead. The spirally twisting horns grow about 4 feet (1.2 meters) long. The addax usually runs in herds of from 5 to 30 animals. It is in danger of extinction due to overhunting. William L. Franklin



© Gail Rubin, Photo Researchers

The addax is an antelope with spirally twisting horns. It lives in North African deserts and travels in herds of 5 to 30 animals.

Scientific classification. The addax belongs to the bovid family, Bovidae. It is *Addax nasomaculatus.*

Adder is the name given to several species of snakes in various parts of the world. Some of these snakes are poisonous. The European *viper* is frequently called "adder" in the United Kingdom. This snake is the only poisonous snake in Britain. The *puff adder* of Africa is a large, deadly snake with distinct markings. It has a

WORLD BOOK illustration by Richard Lewington, The Garden Studio, London

An adder commonly known as the *European viper, shown here,* is the only poisonous snake that is found in the United Kingdom.

Four by Five

Addis Ababa, the capital of Ethiopia, lies in the central part of the country on the southern slopes of the Entoto Mountains. It is Ethiopia's largest city and a major commercial center.

thick body and long fangs. The *death adder* of Australia is a dangerous snake related to cobras. The *hognose snakes* of the United States, whose bite is not deadly to human beings, are commonly called "blowing adders." They get their name from their habit of hissing and flattening the front part of their bodies when they are disturbed. Albert F. Bennett

Scientific classification. Most adders are in the family Viperidae. The European viper is classified as *Vipera berus.* The puff adder is *Bitis arietans.* The death adder belongs to the family Elapidae. It is classified as *Acanthophis antarcticus.* Hognose snakes belong to the family Colubridae and the genus *Heterodon.*

Addiction. See **Drug abuse.**

Addis Ababa, *AD ihs AB uh buh* (pop. 2,084,588), is the capital and largest city of Ethiopia. It is a leading city of Africa and the headquarters of important regional organizations. Addis Ababa lies in central Ethiopia. For location, see **Ethiopia** (map).

Addis Ababa lies on the southern slopes of the Entoto Mountains. Deep ravines cut through the city. Many eucalyptus trees grow in and near Addis Ababa.

Ethiopia's national government occupies the palace of a former emperor, Menelik II, in Addis Ababa. The Jubilee Palace, the residence of former Emperor Haile Selassie I, is in the city. The African Union (AU) and the United Nations Economic Commission for Africa have their headquarters in Addis Ababa. The National Theater, the University of Addis Ababa, and several museums are also in the city.

Homes of wealthy and poor people stand next to each other throughout Addis Ababa. The city's housing ranges from high-rise apartment buildings and European-style homes to traditional African mud huts.

Addis Ababa is an important commercial center and has one of the largest open-air markets in Africa. This market is called the Mercato. The city's products include cement, sugar, textiles, and tobacco. Addis Ababa has an international airport, and a railroad links the capital with Djibouti, a city on the Gulf of Aden. A rapidly growing population and other factors have made unemployment a problem in Addis Ababa.

Addis Ababa was founded in 1887 by Menelik II, who was then king of Shawa Province. Menelik made Addis Ababa the capital of the province. He took the throne as emperor of Ethiopia in 1889, and Addis Ababa became the nation's capital.

Until 1974, much of Addis Ababa's land was owned by the emperor's family, members of the nobility, and the Ethiopian Orthodox Church. That year, a revolution headed by Ethiopian military leaders overthrew Emperor Haile Selassie I. Most of the city's land then came under government control. Kenneth J. Perkins

See also **Ethiopia** (picture: Addis Ababa).

Addison, Joseph (1672-1719), was an English author and politician. He is best known for his collaboration with Sir Richard Steele in writing and publishing *The Spectator,* a series of 555 popular essays published in 1711 and 1712. These essays were intended to improve manners and morals, raise the cultural level of the middle-class reader, and popularize serious ideas in science and philosophy. Most of the essays deal with social behavior, love and marriage, and literature. Addison wrote with charm and polish, and Steele with liveliness and feeling. See **Steele, Sir Richard.**

The Spectator became popular because it expressed in a natural but sophisticated manner the ideals admired by its readers. The essays also gave middle-class readers a pleasant sense of self-improvement in manners and taste. To add to the interest of the essays, Addison and Steele introduced a set of representative English characters. The most famous of these characters was the simple but delightful country squire, Sir Roger de Coverley.

Addison also contributed to *The Tatler* (1709-1711), a periodical started by Steele. Addison's verse tragedy, *Cato* (1713), ran for a month on the London stage and was admired for its patriotic sentiments.

Addison was born in Milston in Wiltshire on May 1, 1672. While attending Oxford University from 1687 to 1699, he earned a reputation as a classical scholar. He was rather reserved, but his personal charm and wit won him powerful friends in London. He entered politics after achieving sensational success with a patriotic poem, "The Campaign" (1704), describing the English vic-

tory in the Battle of Blenheim. He served in Parliament from 1708 until his death and also held several government appointments. In 1717, Addison was appointed secretary of state. Illness forced him to resign in 1718.

Gary A. Stringer

Addison, Thomas (1793-1860), was a British doctor famous for his description of Addison's disease (see **Addison's disease**). Addison reported this condition, in which bronzed skin is found together with diseased adrenal glands, in a research paper in 1855. He also described Addison's anemia, known today as *pernicious anemia* (see **Anemia**).

During his lifetime, Addison's reputation rested largely on his outstanding ability as a doctor and teacher. His painstaking examinations of patients and his uncanny diagnoses became a legend.

Addison was born near Newcastle, England. He obtained his medical degree at the University of Edinburgh in 1815 and started his practice in London. In 1824, Addison was appointed assistant physician at Guy's Hospital in London. He began teaching and conducting clinical medical studies there, and his work eventually made Addison a leading figure in British medicine.

Dale C. Smith

Addison's disease is a disorder that gradually destroys the adrenal glands, causing them to produce insufficient amounts of certain hormones. The body has two adrenal glands, one located on top of each kidney. The most common cause of Addison's disease is an *autoimmune disorder* in which the body's immune system attacks and destroys the adrenal glands. Other causes of Addison's disease include cancer, infectious diseases such as tuberculosis, and such fungal diseases as histoplasmosis. Addison's disease is named after the British doctor Thomas Addison, who first described the disorder in 1855.

Addison's disease develops gradually, and patients are unable to say exactly when their symptoms began. Almost all patients experience weakness and fatigue, and most suffer weight loss. Many patients experience nausea, vomiting, and diarrhea. The disease also is characterized by abnormal skin *pigmentation* (coloration). In most patients, the skin becomes darker than normal. Abnormal pigmentation may be especially evident in areas of the body exposed to light.

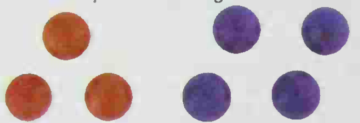
Doctors treat Addison's disease by prescribing drugs to replace the missing hormones. One of the most widely used drugs is hydrocortisone. The majority of patients who receive treatment can live full, active lives.

David L. Reiss

Addition is a way of putting together two or more things to find out how many there are all together. Only *like things* can be added. This is, you cannot add apples and pencils together.

Suppose you have a set of 5 apples and a set of 3 apples on a table:

Now put the sets together in a new set of 8 apples.



You *add* when you put together two or more sets to find out how many there are all together.

Learning to add

To find out how many things you have added to make a new set, you can *count* them or *think* them together.

Addition by counting. Ralph has 3 red marbles and 4 blue marbles. He puts them together in one set.

How many marbles are there in the first set? Count them. There are 3 marbles. How many marbles are there in the second set? Count them. There are 4 marbles. Now, put the marbles together and count them in the third set. There are 7 marbles. We call this *counting together.* You counted to find how many 3 marbles and 4 marbles are together. You discovered that 3 and 4 are 7.

Suppose you have drawn 3 circles. Now draw 4 more circles next to the first 3.

You know that there were already 3 circles. So you can think "3" and point to each of the 4 new circles, and count "4, 5, 6, 7." This is called *counting on.* You can find out how many 3 and 4 are together by thinking "3" for the first set, and counting on until you have counted the 4 circles in the second set. Counting on serves as a quicker way of adding things than counting them together.

Addition by thinking. Suppose there are 4 girls at the blackboard and 5 girls at the reading table. You find how many girls there are all together by thinking. For example, you could think: "I already know that 4 and 4 are 8, so 4 and 5 will be 1 more. That means that 4 and 5 are 9." Or, you could think: "4 girls and 5 girls are 9 girls." We call this *thinking together.* Thinking together is a quicker way of adding than counting together or counting on.

Addition terms

Addend. In $4 + 9 = 13$, the numbers which are added, 4 and 9, are both addends.
Addition fact is a basic statement in addition. For example, $2 + 3 = 5$ and $8 + 7 = 15$ are addition facts.
Carry in addition means to transfer a number from one place in the sum to the next. A 10 in the 1's place must be carried to the 10's place.
Sum. In $4 + 9 = 13$, the total, 13, is the sum.

Regrouping. Suppose you want to put together two sets in a new set and the new set will be more than 10. For example, Nancy wanted to know how many 9 and 6 are. To find out, she drew a *number line:*

Then, she drew lines to show 9 and 6 as shown below:

9 6

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17

Nancy found out that 9 and 6 are 15. But she saw something interesting and drew two more lines:

10 5

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17

9 6

Nancy found that 9 and 6 are the same as 10 and 5. It is easier for beginners to add 10 and 5 than it is to add 9 and 6. We call changing the sets 9 and 6 to the sets 5 and 10 *regrouping*. Here are some examples:

8 and 4 are 12	(10 and 2)
7 and 8 are 15	(10 and 5)
9 and 4 are 13	(10 and 3)

Writing addition. You should write down your addition problems, so you have a record of your counting or thinking.

You can make a record with pictures:

Or you can make a record with numbers and words:

2 and 4 are 6

But it is easiest and best to make a record with numbers and signs:

$2 + 4 = 6$ or $\begin{array}{r} 2 \\ \underline{4} \\ 6 \end{array}$

In the first example, the plus sign (+) tells you to add. You can read 2 + 4 as "two and four." The equals sign (=) means that the sets on one side of the sign are *equal* to the set on the other side of the sign. You can read 2 + 4 = 6 as "two and four are six." The second example shows how you write an addition problem when you want to work out the answer on paper. The two or more groups you want to put together, or add, are called *addends*. The new group is called the *sum*.

2	*Addend*
4	*Addend*
6	*Sum*

Addition facts. By putting together sets, you have discovered that 5 + 3 = 8, 3 + 4 = 7, and 9 + 6 = 15. We call these *addition facts*. Each addition fact is made up of two addends and a sum. You can discover all the addition facts by putting together sets of things. Some beginners practice with sets of pennies or bottle caps.

The 81 addition facts

1	1	1	1	1	1	1	1	1
1	2	3	4	5	6	7	8	9
2	3	4	5	6	7	8	9	10
2	2	2	2	2	2	2	2	2
1	2	3	4	5	6	7	8	9
3	4	5	6	7	8	9	10	11
3	3	3	3	3	3	3	3	3
1	2	3	4	5	6	7	8	9
4	5	6	7	8	9	10	11	12
4	4	4	4	4	4	4	4	4
1	2	3	4	5	6	7	8	9
5	6	7	8	9	10	11	12	13
5	5	5	5	5	5	5	5	5
1	2	3	4	5	6	7	8	9
6	7	8	9	10	11	12	13	14
6	6	6	6	6	6	6	6	6
1	2	3	4	5	6	7	8	9
7	8	9	10	11	12	13	14	15
7	7	7	7	7	7	7	7	7
1	2	3	4	5	6	7	8	9
8	9	10	11	12	13	14	15	16
8	8	8	8	8	8	8	8	8
1	2	3	4	5	6	7	8	9
9	10	11	12	13	14	15	16	17
9	9	9	9	9	9	9	9	9
1	2	3	4	5	6	7	8	9
10	11	12	13	14	15	16	17	18

It is best to learn the addition facts so you can use them quickly and easily. You will be able to use them in your daily life. You will also need them to add larger numbers and solve problems.

Learning these addition facts looks like work at first. But there are several ways to make learning the facts easier. For instance, if you look at all the facts in which a number and 1 are added, you will see that learning them is something like ordinary counting. Also, many of the pairs of addends are just the *reverse* of each other. For example, 4 + 5 adds up to the same thing as 5 + 4. We call a fact like 3 + 3 = 6 a *double*. Knowing doubles is useful. If you know that 4 + 4 = 8, then 4 + 3 is 1 less than 8, and 4 + 5 is 1 more than 8. You should be able to think of other ways to help you learn the addition facts.

Adding larger numbers

You use the addition facts and the idea of place value to add larger numbers.

Adding 10's. Last week, Tom earned 2 dimes, or 20¢. This week, Tom earned 3 dimes, or 30¢. How much has

Tom earned all together? You can find the answer by counting.

1

2

3

4

5

You find that Tom earned 5 dimes, or 50¢. You can find the answer by adding.

2 dimes	20¢
3 dimes	30¢
5 dimes	50¢

If you know that 2 + 3 = 5, you know that 2 dimes and 3 dimes are 5 dimes. A dime is 10¢, so you can see that 20¢ + 30¢ = 50¢.

Here is another example:

4	4 tens	40
2	2 tens	20
6	6 tens	60

You can see that 4 + 2 = 6, 4 tens + 2 tens = 6 tens, and 40 + 20 = 60. The 6 in the 60 shows six 10's because it is in the 10's place. *You add 10's the same way you add 1's. But you must write the sum in the 10's place.* And you must remember to write a zero in the 1's place to show that the sum is 10's, not 1's.

Here is a third example:

8	8 tens	80
9	9 tens	90
17	17 tens	170

Here the sum of the 10's is seventeen 10's. Seventeen 10's is the same as ten 10's and seven 10's. But ten 10's is 100. So you must write the sum in the 10's and 100's places, and write in a zero to show that the answer is one 100, seven 10's, and no 1's.

Adding 10's and 1's. Suppose there are 23 boys and 24 girls in a school play. To find out how many children there are all together, you must add 23 and 24.

2 tens and 3 ones	23
2 tens and 4 ones	24
4 tens and 7 ones	

We call the numbers 23 and 24 *two-place numbers*. When you add two-place numbers, you add the 1's first. In this example, three 1's and four 1's are 3 + 4 = 7. You write the sum of the 1's in the 1's place of the answer:

23
24
 7

Next, you add the 10's. Two 10's and two 10's are added as 2 + 2 = 4. The 4 stands for four 10's. You write the sum of the 10's in the 10's place of the answer:

23
24
47

So there are 47 children in the school play.

Here is another example:

72
43
115

First, you add the 1's: 2 + 3 = 5. Next, you find that seven 10's and four 10's are eleven 10's. Eleven 10's are the same as ten 10's and one 10, or one 100 and one 10. So you must write the sum of the 10's in the 10's and 100's places in the answer.

When there are several addends, we often speak of the 1's, 10's, and 100's as *columns*. When you add columns, you must learn to *think* the additions. At first it may help to keep some kind of record.

22 31 45 98	1's	**Think:** 2 + 1 = 3. 3 + 5 = 8. **Write:** 8 in the 1's place.
	10's	**Think:** 2 tens + 3 tens = 5 tens. 5 tens + 4 tens = 9 tens. **Write:** 9 in the 10's place.

With practice, adding two-place numbers and long columns will be easy.

How to carry. When you add two-place numbers, the sum of the 1's column is often 10 or more. To add such numbers, you must learn to *carry*.

Here is an example of carrying:

45 27 2	1's	**Think:** Five 1's and seven 1's are twelve 1's: 5 + 7 = 12. Twelve is one 10 and two 1's. **Write:** 2 in the 1's place.
	CARRY	From the 1's column, there is a 10 to be added to the 10's column. Write a 1 for the one 10 at the top of the 10's column. This is what *carrying* means.
1 45 27 72	10's	**Think:** One 10 + four 10's + two 10's = seven 10's. 1 + 4 + 2 = 7. **Write:** 7 in the 10's place.

You add longer columns the same way.

24
52
17

First, add the 1's column: 4 + 2 = 6, and 6 + 7 = 13. Thirteen is one 10 and three 1's. Write the 3 in the 1's place of the answer. Carry the one 10 to the 10's column by writing a 1 at the top of the 10's column.

1
24
52
17
 3

Now add the 10's column: 1 + 2 = 3, 3 + 5 = 8, and 8 + 1 = 9. This 9 means nine 10's. Write the 9 in the 10's place.

```
 1
24
52
17
--
93
```

Adding three-place and four-place numbers is no more difficult than the examples you have just done. You must always remember to keep the columns straight, and to add 1's, 10's, 100's, and so on, in order. Here is an example:

```
371
403
139
---
```

First, add the 1's column: 1 + 3 + 9 = 13. Write 3 for three 1's in the 1's place of the answer. Carry the 10 by writing 1 for one 10 at the top of the 10's column.

```
 1
371
403
139
---
  3
```

Next, add the 10's column: 1 + 7 + 0 + 3 = 11. This is *not* eleven 1's. It is eleven 10's. Eleven 10's is one 100 and one 10. So write 1 for the one 10 in the 10's place of the answer. Carry the 100 by writing 1 for one 100 at the top of the 100's column.

```
11
371
403
139
---
 13
```

Now add the 100's column: 1 + 3 + 4 + 1 = 9. This 9 is nine 100's. Write 9 in the 100's place of the answer.

```
11
371
403
139
---
913
```

The sum is 913. You use the same method of carrying for 1,000's and larger numbers.

Here is an example in which the number you carry is more than one 10:

```
37
29
18
--
```

First, add the 1's column: 7 + 9 + 8 = 24. Twenty-four is two 10's and four 1's. Write the 4 in the 1's place in the answer. Carry the two 10's to the 10's column by writing a 2 at the top of the 10's column.

```
2
37
29
18
--
 4
```

Now add the 10's column: 2 + 3 + 2 + 1 = 8. This 8 means eight 10's. Write the 8 in the 10's place of the answer.

```
2
37
29
18
--
84
```

The sum is 84. The numbers you carry may often be 20's or 30's or 40's, and so on.

Checking addition

Good workers always check their addition to see if they have made any mistakes. There are several ways to check addition.

Adding up. You have learned to add a column of figures by starting at the top and adding down. After you have written the sum, you can check your answer by *adding up*. That is, starting at the bottom of the column and adding up to the top. Here is an example:

```
21
34
42
--
97
```

CHECK	
1's	2 + 4 = 6. 6 + 1 = 7
10's	4 + 3 = 7. 7 + 2 = 9

If you get the same answer adding up as you did adding down, your answer is probably right.

Subtraction can be used to check problems with only two addends (see **Subtraction**). Here is an example:

```
 422
+736
----
1158
```

To check the addition, subtract one of the addends from the sum. For example, subtract 736 from 1,158. The subtraction should leave 422 if the addition is correct:

```
1158
—736
----
 422
```

Estimating is a good way of checking addition, but it will not catch small mistakes. If you estimate before you work a problem, you will have an idea of your answer in advance. You should get into the habit of always estimating your answer first. Here is an example:

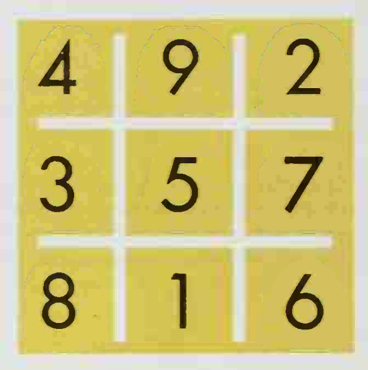
```
 32
 46
 71
---
149
```

ESTIMATING
(Think)
32 is about 30.
46 is about 50.
30 and 50 are 80.
71 is about 70.
80 and 70 are 150.
The answer should be about 150.

There are other methods of checking used in arithmetic. Some of them can be used for addition.

Addition rules to remember

1. Remember what addition means. You can find the answers to addition problems by counting. But it is quicker and easier to *think* the answers.
2. Learning the 81 addition facts will help you think the answers to addition problems.
3. You can put the addends in any order without changing the sum of the equation. For example, $3 + 2 + 7 = 12$, $2 + 7 + 3 = 12$, and $7 + 3 + 2 = 12$.
4. You can add only quantities of the same kind. That is, you must add 1's to 1's and 10's to 10's, and be careful not to mix them up.



Fun with addition

Two winks. Make a pack of 20 cards on which the numbers from 1 to 10 have been written. Make two cards for each number. Divide the pack of cards into two piles, and put one pile face down in front of each player. The first player turns a card and holds it up for both players to see. The second player does the same thing from the other pile of cards. The player who first sees that the sum of the numbers on the two cards is 10 or more calls out "Two winks!" Then, that player takes

the two cards. If the two cards do not equal 10 or more, the players put them back in the piles. The game continues, with two new players turning the cards. When all of the cards have been turned, the player with the most cards wins.

Tick-tack-toe puzzle. Each player draws a tick-tack-toe figure on a piece of paper.

Then, each tries to fill in the spaces with the numbers from 1 to 9, so that if three numbers are added across, up and down, or diagonally the sums will be 15. The player must use each number from 1 to 9. The first player with the correct answer wins.

Address, Forms of, are courteous, formal ways to introduce, speak to, write to, or send e-mail to other people. In most cases, you can address another person as "Mr. Green" or "Ms. Green" or by using that person's title before his or her last name. In business correspondence, use "Miss" or "Mrs." only when you know that the recipient prefers such a form of address. Government officials, members of royalty, religious dignitaries, and members of certain professions merit special forms of address. This article gives some of the most commonly used forms of address for people in such positions.

"Yours truly" is a common closing for letters, though there are many others. Certain situations require a more formal closing such as "Respectfully yours."

In the examples listed here, the first indentation under each entry provides the formal way to introduce or refer to the person in each position. The second indentation gives the proper salutation to use for communicating with the person in writing or by e-mail. An acceptable closing is also included for positions in which "yours truly" is considered insufficiently formal.

Officials of the United States

President
The President
Dear Mr. *or* Madam President:
Closing: Respectfully,

Vice president
The Vice President
Dear Mr. *or* Madam Vice President:

Cabinet member (except attorney general)
The Honorable John *or* Mary Green, Secretary of (State *or* Transportation, for example)
Dear Mr. *or* Madam Secretary: *or* Dear Secretary Green:
(Deputy secretaries, assistant secretaries, and undersecretaries are addressed by their specific title, but the salutation is "Dear Mr. *or* Ms. Green:".)

Assistant to the president
The Honorable John *or* Mary Green *or* Assistant to the President Green
Dear Mr. *or* Ms. Green:

Attorney general
The Attorney General
Dear Mr. *or* Madam Attorney General:

Chief justice of the United States
The Chief Justice of the United States
Dear Mr. *or* Madam Chief Justice:

Associate justice of the Supreme Court
Justice Green
Dear Mr. *or* Madam Justice: *or* Dear Justice Green:

United States senator
The Honorable John *or* Mary Green
Dear Senator: *or* Dear Senator Green:

United States representative
The Honorable John *or* Mary Green
Dear Mr. *or* Ms. Green: *or* Dear Representative Green: *or* Dear Congressman *or* Congresswoman Green:

Speaker of the House of Representatives
The Honorable John *or* Mary Green
Dear Mr. *or* Madam Speaker:

Member of an agency, bureau, or commission
The Honorable John *or* Mary Green
Dear Mr. *or* Madam Chairman: *or* Dear Mr. *or* Ms. Green:
(For a commissioner, the salutation is generally "Dear Commissioner Green:".)

Ambassador
The Honorable John *or* Mary Green, Ambassador of the United States of America
Sir *or* Madam: *or* Dear Mr. *or* Madam Ambassador:
Closing: Very truly yours,
(Although it is permissible to refer to a United States ambassador as "American Ambassador," it is best not to do so because other Western Hemisphere ambassadors also consider themselves Americans. Ministers, chargés d'affaires, consuls, and secretaries all use their full title in place of "Ambassador" but are addressed as "Dear Mr. *or* Ms. Green:".)

Governor of a state
The Honorable John *or* Mary Green
Dear Sir *or* Madam: *or* Dear Governor Green:

State senator
The Honorable John *or* Mary Green
Dear Sir *or* Madam: *or* Dear Senator Green:

State representative
The Honorable John *or* Mary Green
Dear Sir *or* Madam: *or* Dear Representative Green:

Mayor or city manager
The Honorable John *or* Mary Green
Dear Sir *or* Madam: *or* Dear Mayor Green:
(City managers do not use "Honorable" except at ceremonies. They are addressed as "Mr. John Green" *or* "Ms. Mary Green" and "Dear Mr. Green" *or* "Dear Ms. Green".)

Officials of the Commonwealth of Nations

King or queen
His *or* Her Majesty
Your Majesty: *or* Madam:
Closing: Respectfully, *or* Respectfully yours,

Prince or princess
His Royal Highness, the Prince John *or* Her Royal Highness, the Princess Mary
Your Royal Highness:
Closing: Respectfully, *or* Respectfully yours,

Knight or dame
Sir John Green *or* Dame Mary Green
Dear Sir John Green *or* Dear Dame Mary Green:
(A knight's or dame's name is followed by initials that designate the order of knighthood. For example, *KCB* or *DCB* stand for *Knight Commander of the Bath* or *Dame Commander of the Bath*, and *KG* or *DG* stand for *Knight of the Garter* or *Dame of the Garter*.)

Prime minister
The Right Honourable John *or* Mary Green, Prime Minister of (Canada or the United Kingdom, for example)
Dear Sir *or* Madam: *or* Dear Prime Minister:
Closing: Respectfully yours, *or* Very truly yours,

Member of the House of Lords of the United Kingdom
The Right Honourable the (Duke *or* Earl *or* Viscount, for example) Green
My Lord:

Member of the House of Commons
John *or* Mary Green, M.P.
Dear Sir *or* Madam:

Governor general
His *or* Her Excellency the Right Honourable John *or* Mary Green, Governor General of (Canada, for example)
Dear Sir *or* Madam: *or* Sir *or* Madam:

Premier or prime minister of a province
The Honourable John *or* Mary Green, Prime Minister of (Ontario, for example)
Dear Sir *or* Madam: *or* Sir *or* Madam:

Senator
The Honourable John *or* Mary Green
Dear Sir *or* Madam:

Minister of a department
John *or* Mary Green, Minister of (Transport, for example)
Dear Sir *or* Madam:

Judge
The Honourable Mr. Justice John Green *or* The Honourable Ms. Justice Mary Green
Dear Justice Green:
(A High Court judge is addressed as "Your Lordship" or "My Lord" only when the court is in session. An English or Australian

justice of the peace on the bench is addressed in court as "Your Worship." In Canada, judges for county and district courts are addressed as "His *or* Her Honour Judge Green:")

Mayor

His Worship Mayor John Green *or*
Her Worship Mayor Mary Green
Dear Sir *or* Madam: *or* Dear Sir *or* Madam Mayor:

President

The Right Honourable John or Mary Green, President of the Republic
Dear Sir *or* Madam: *or* Dear Sir *or* Madam President:

Foreign officials in the United States

Ambassador to the United States

His *or* Her Excellency John or Mary Green, Ambassador of (Australia, for example)
Dear Mr. *or* Madam Green: *or* Dear Mr. *or* Madam Ambassador:

Secretary-general of the United Nations

His *or* Her Excellency John *or* Mary Green, Secretary-General of the United Nations
Sir *or* Madam: *or* Dear Mr. *or* Madam Secretary-General:

(Ambassadors and representatives to the United Nations use the form "Representative of Brazil to the United Nations.")

Representative to the United Nations

You may use the forms of address for Ambassador as a general guide for addressing United Nations representatives. However, each member nation awards its own titles to its individual representatives to the United Nations. Whenever possible, the representatives should be addressed by the titles conferred by their country.

Members of the clergy

Roman Catholic archbishop or bishop

Your excellency *or* Archbishop Green
Your excellency *or* Bishop Green
Archbishop *or* Bishop of (Chicago, for example)
Dear Archbishop *or* Bishop Green:

(Episcopal bishops often use "The Right Reverend." Greek Orthodox bishops often use "The Very Reverend.")

Roman Catholic cardinal

His Eminence John Cardinal Green
Your Eminence: *or* My Dear Cardinal Green:

Roman Catholic priest

The Reverend Father John Green
Dear Father Green: *or* Reverend Father:

Roman Catholic nun

Sister Mary Xavier, T.O.S.F.
Dear Sister Xavier:

Church of England archbishop

The Most Reverend John Green, the Lord Archbishop of (Canterbury, for example)
Your Grace: *or* My Dear Archbishop:

Church of England bishop

The Right Reverend John Green, the Lord Bishop of (Bristol, for example)
My Lord: *or* My Lord Bishop:

Church of England priest

The Reverend John Green
Dear Father Green:

Church of England canon

The Reverend Canon John Green
Dear Canon Green:

Protestant minister

The Reverend John *or* Mary Green
Dear Reverend Green:

(If a minister has a doctor's degree from a university, it is often used in the salutation in place of "Reverend," as "Dear Doctor Green:".)

Rabbi

Rabbi Jacob *or* Miriam Green
Dear Rabbi Green:

Other forms

President or chancellor of a university or college

President *or* Chancellor John Green *or* President *or* Chancellor Mary Green
Dear President *or* Chancellor Green:

Professor

Professor John *or* Mary Green
Dear Professor Green:

(Full professors, associate professors, and assistant professors can be addressed as "Professor." Lecturers, instructors, and fellows are addressed as "Mr." or "Ms.")

Lawyer

John R. Green, Esq.
Dear Mr. Green:

(Attorneys, especially in the United States, usually address each other by "Esq." This abbreviation stands for "esquire." In the United Kingdom, Queen's Counsel add the initials Q.C. after the name.)

Doctor of medicine or dentistry

Medicine: Dr. John *or* Mary Green, *or* John *or* Mary Green, M.D.
Dentistry: Dr. John or Mary Green, or John or Mary Green, D.D.S.

(In the United States, all medical doctors and dentists are addressed as "Dr." In the United Kingdom, surgeons and specialists are more often addressed as "Mr." Dentists are rarely addressed as "Dr.")

Doctor of veterinary medicine:

Dr. John *or* Mary Green, *or* John *or* Mary Green, D.V.M.
Dear Dr. Green:

Doctor of an academic discipline

Dr. John *or* Mary Green, *or* John *or* Mary Green, Ph.D. or Ed.D.
Dear Dr. Green:

(People outside the medical and health professions who hold a doctorate may choose whether or not to be addressed as "Dr.")

Military officer

Captain John *or* Mary Green, U.S. Coast Guard
Dear Captain Green:

(All people who hold rank that has subgrades, such as vice admiral, second lieutenant, or master sergeant, are addressed by their rank without qualification—as, for example, "Dear Admiral:", "Dear Lieutenant," *or* "Dear Sergeant:".)

Widow

Mrs. John Green
Dear Mrs. Green:

(If a widow or a divorced woman signs her own name to a letter "Mrs. Betty Green," then the person writing to this woman should use the same form of address.) Deborah Dumaine

See also **Letter writing**.

Ade, *ayd,* **George** (1866-1944), was an American humorist, playwright, and journalist. He won fame for his comic stories written in the everyday speech and popular slang of the rural Midwest, especially his home state of Indiana.

Ade's best-known work is *Fables in Slang* (1899), a collection of stories modeled on *Aesop's Fables*. The work consists of humorous tales of country life and of country people living in the city. It also makes fun of show-offs and bigots.

Ade was also a noted comic playwright and author of musical comedies. His most successful works for the musical stage were *The Sultan of Sulu* (1902) and *The Sho-Gun* (1904). His most significant plays were two comedies of small-town life in the United States, *The County Chairman* (1903) and *The College Widow* (1904). Although Ade's theater works are rarely staged today, they provide a significant record of American life in the early years of the 1900's.

Ade was born in Kentland, Indiana. In the 1890's, he

worked as a reporter for the Chicago *Record.* Many of his stories originally appeared in a column he wrote for the newspaper. Samuel Chase Coale

Adelaide, *AD uh LAYD* (pop. 1,045,854), is the state of South Australia's capital, largest city, economic center, and chief port. It lies on a plain on Australia's southern coast and extends inland from the Gulf of St. Vincent, an inlet off the Indian Ocean. For the location of Adelaide, see Australia (political map). It was named for Queen Adelaide, whose husband, William IV, ruled Britain from 1830 to 1837.

The River Torrens flows through Adelaide. The city's central business district is on both banks of the river, 6 miles (10 kilometers) inland from the Gulf of St. Vincent. A belt of beautiful parkland surrounds the central business district. Adelaide's residential, commercial, and industrial areas spread north and south along the plain. The Mount Lofty Ranges rise east of the city.

Manufacturing is the area's chief economic activity. Products manufactured include household appliances, motor vehicles, electrical goods, and processed foods. Adelaide hosts an international Festival of the Arts every two years.

Adelaide was first settled by Europeans in 1836. Colonel William Light, the first surveyor general of South Australia, completed a city plan for Adelaide in 1837. The city quickly became an important center for nearby agricultural and mining activities. A large number of new industries were established in Adelaide after World War II ended in 1945. The city's population has grown greatly since then and now accounts for more than 70 percent of South Australia's population.

Garry R. LeDuff

Aden, *AHD uhn* or *AYD uhn* (pop. 318,000), is the second largest city of Yemen. Only Sanaa has more people. Aden lies on a small peninsula that extends into the Gulf of Aden. For the location of Aden, see Yemen (map). Aden has served as an important port and trading center since ancient times.

Aden has both broad streets lined by Western-style buildings and winding, narrow streets bordered by old, thick-walled Arab buildings. The city serves as the trading center for its region and as a refueling place for ships. It has a large oil refinery. Manufactured products include cooking oil and textiles.

Aden became an important Roman trading center during ancient times. In 1839, British forces took over the city. In 1967, Yemen (Aden) became an independent nation with Aden as its capital. In 1990, Yemen (Aden) and Yemen (Sanaa) merged and became the country of Yemen, with Sanaa as the capital. Robert Geran Landen

Adena Indians. See Mound builders.

Adenauer, *AH duh NOW uhr,* **Konrad** (1876-1967), served as chancellor of the West German Republic from its formation in 1949 until he retired in 1963. Under his leadership, West Germany gained its sovereignty, made an extraordinary economic recovery, built its military power, and played a major role in Western European affairs. Adenauer's accomplishments were all the more remarkable because he was 73 years old when he started his 14 years as chancellor.

Adenauer helped bring Germany into the North Atlantic Treaty Organization (NATO), the Council of Europe, the European Coal and Steel Community, and the European Economic Community. Adenauer allied his country with the Western powers. He acknowledged Germany's responsibility for the crimes committed against the Jews during World War II, and Germany paid war reparations to the Jewish state of Israel. Adenauer and French President Charles de Gaulle signed a Franco-German Treaty of Cooperation in 1963. The treaty was seen as a symbol of reconciliation between France and Germany, which had traditionally been enemies.

Wide World

Konrad Adenauer

As chancellor, Adenauer exercised strong rule. He treated his ministers as subordinates rather than as his colleagues. During his later years as chancellor, Adenauer's actions were criticized both by his own Christian Democratic Union Party members and by his opponents.

Adenauer was born on Jan. 5, 1876, in Cologne, Germany. He studied at the universities of Freiburg, Munich, and Bonn, and became a lawyer. He served as mayor of Cologne from 1917 to 1933. During World War II, the Nazis imprisoned him several times.

The Allies made Adenauer mayor of Cologne when they occupied Germany after World War II. However, the British dismissed him, and Adenauer entered national politics in 1947 as the leader of the Christian Democratic Party. He played an important role in drafting the West German constitution, which went into force in 1949. That year, Adenauer won his first election as chancellor. After Adenauer retired in 1963, his vice chancellor, Ludwig Erhard, was elected chancellor.

Adenine. See Cell (The code of life).

Adenoids, *AD uh noydz,* also known as *pharyngeal tonsils,* are a mass of glandlike tissue normally present in the upper part of the throat, directly behind the nasal passages. A small amount of this tissue is always found in the throats of newborn babies. Usually it shrinks gradually and disappears by the time the child is 10 years old. But sometimes this shrinking process does not take place. Instead, the adenoid tissue increases in varying degrees to form a large growth. It is this growth that people commonly call "adenoids."

The adenoid tissue may grow so extensively that it fills the entire space behind the nose and interferes with nasal breathing. The soft, spongy tissue harbors germs and becomes infected easily. The infecting organisms often cause additional swelling so that the whole upper part of the throat may become clogged. Then breathing through the nose becomes almost impossible, and the whole area is inflamed and sore.

Enlarged adenoid tissue also may block the *Eustachian tube* that connects the back of the throat and the middle ear. Fluid then forms in the middle ear, resulting in a condition that is known as *serous otitis media.* This condition may lead to hearing loss and recurrent ear infections. See Ear (Diseases).

Like the other tonsils, the adenoids consist of lym-

WORLD BOOK illustration by Charles Wellek

The adenoids, or *pharyngeal tonsils,* are in the upper part of the *pharynx* (throat). They sometimes become enlarged and inflamed, causing difficulties in breathing through the nose.

phoid tissue (see **Lymphatic system**). The adenoids and other tonsils form a continuous ring of lymphoid tissue around the back of the throat. If adenoid tissue causes repeated infections, doctors may remove it in a surgical operation called an *adenoidectomy.* Jerome C. Goldstein

See also **Tonsil.**

Adhesion, *ad HEE zhuhn,* is the property of two unlike substances that causes them to stick together. Adhesion occurs because of the attraction between all molecules and atoms.

Adhesive strength varies, depending on the characteristics of the substances coming together. The adhesion between the surfaces of two solid substances tends to be low, even if they seem perfectly flat and clean. The surfaces are actually rough when viewed through a microscope, and touch each other at relatively few places. But if one of the substances is part or all liquid, contact between the surfaces is much greater.

The strongest adhesives are applied as thin layers of liquids. In many cases, these liquids are solutions of *polymers* (compounds of high molecular weight). As these solutions set, their molecules become immovable. The adhesion can be so good that a strong force will cause the substance, but not the adhesive bond, to break. James Nelson Rieck

See also **Cohesion.**

Adhesion, *ad HEE zhuhn,* in the body, is a name for new tissue that sometimes binds together internal organs that are normally separate. Such tissue usually grows as a result of inflammation or a surgical operation. Adhesions are often painful and may interfere with the normal work of the internal organs. Diseases of the heart or lungs may result in painful adhesions between those organs and the surrounding parts of the body. After abdominal operations, adhesions sometimes cause portions of the intestine to grow together or to the lining of the abdomen. If the adhesions interfere with digestion, additional surgical operations may be necessary. See also **Tissue.** David T. Woodley

Adhesive is a substance that bonds surfaces together. Adhesives include such materials as cement, epoxy, paste, polyurethane, white glue, and *cyanoacrylate* (super glue). Adhesives are used in homes, offices, and schools. They also play an important role in the manufacture of many products, including aircraft, automobiles, books, furniture, and toys. In addition, they are used in the construction of buildings and roads. Many people use adhesives to make simple household repairs.

Since ancient times, people have made adhesives from such natural materials as beeswax, egg yolks, tree sap, and proteins from animal hides, hooves, and blood. Today, most adhesives are made from plastics and other synthetic materials.

Adhesives vary in the way they are applied and in the manner in which they form a bond. For example, adhesives made from the synthetic materials *polyethylene* and *polyvinyl acetate,* called *hot melt adhesives,* are heated to a liquid state before being applied. The bond forms as the adhesive cools and hardens. Epoxy adhesives are usually sold as two substances in separate tubes. The two substances must be mixed before being applied to the surfaces to be joined. The molecules of epoxy adhesives *cross-link* (interconnect) to form a *thermoset material,* which cannot be deformed by heat or pressure. Cyanoacrylate reacts with water on the joined surfaces to create a strong, but brittle, adhesive bond.

Daryl J. Doyle

Adirondack Mountains, *AD uh RAHN dak,* are a group of mountains that cover about 12,000 square miles (31,000 square kilometers) in northeastern New York. Millions of tourists, hikers, and sports enthusiasts are drawn every year to the Adirondacks for its beautiful scenery, wildlife, and recreational opportunities.

More than 40 of the Adirondack Mountains rise above 4,000 feet (1,200 meters). Mount Marcy, at 5,344 feet (1,629 meters), is the highest point in New York. Lake Champlain and Blue Mountain Lake are among the hundreds of lakes that dot the region. Lake George and Lake Placid are famous resort areas.

The mountains were formed when powerful geologic forces lifted the earth's crust more than a billion years ago. Glaciers later created most of the region's lakes. Adirondack Park has 6 million acres (2.4 million hectares) of public and private lands. The 2 $\frac{1}{2}$ million acres (1 million hectares) of public land makes up the largest wilderness preserve in the eastern United States. The word *Adirondack* comes from the Iroquois Indian word for *bark eater.* The Iroquois may have used this term to describe the neighboring Algonquin Indians. Michael K. Heiman

See also **Lake Champlain; Lake Placid; New York** (picture).

Adjective is a part of speech that describes, qualifies, or places limits on a noun or pronoun. Adjectives are said to *modify* nouns or pronouns.

As a part of speech, adjectives are single words. However, clauses and phrases may serve roughly the same function. For example, in *the angry woman* and *the woman angered by his crude behavior,* the phrase *angered by his crude behavior* modifies the noun *woman,* just as the word *angry* does. Relative clauses generally function as adjectives. For example, in "The man *whose sister is arriving from France,*" the relative clause *whose sister is arriving from France* modifies *the*

man. These clauses and phrases that serve as adjectives are called *adjectival* clauses and phrases.

A speaker or writer uses adjectives to add detail, to make distinctions, and to be precise about what they are saying. For example, various adjectives can make the noun *tulip* more and more specific. *A red tulip* adds a quality. *A big, beautiful, red tulip* adds even more detail. Sometimes the effects are more dramatic. *An alleged murderer* is not necessarily a murderer. *A false prophet* is not a prophet at all.

The position of adjectives. Adjectives can occupy three different positions in a sentence. An adjective can come before a noun, as in *wild animal.* Or an adjective can follow a noun, as in the title *Captains Courageous.* When adjectives are themselves modified by a prepositional phrase, the adjective and prepositional phrase follow the noun *(The wet shirt* versus *The shirt wet with perspiration).*

Adjectives can also follow a *linking verb.* Linking verbs include the verb *to be* and such verbs as *seem, become, feel,* or *taste.* In the sentence *The furniture is durable,* the adjective *durable* follows the linking verb *is* and modifies the noun *furniture.*

Adjectives that follow a linking verb are called *predicate adjectives.* Adjectives that follow nouns and repeat the meaning of the noun in different words are called *adjective appositives.* For example, *The boring lecture,* long and dull, *lasted until 9 p.m.*

Comparison of adjectives. Adjectives show differences in amount or degree by the addition of *function words* or by changes in form. The function words *less* and *least* show decreasing amounts or degrees. The function words *more* and *most* show increasing amounts or degrees. Adjectives have three degrees of comparison, called the *positive,* the *comparative,* and the *superlative.* Some adjectives, usually those of one or two syllables, add *-er* to form the comparative and *-est* to form the superlative, as shown in the following examples:

Positive	Comparative	Superlative
dry	drier	driest
free	freer	freest
happy	happier	happiest
high	higher	highest
rich	richer	richest
slow	slower	slowest
warm	warmer	warmest

The comparative and superlatives here show increasing amounts or degrees. Adjectives of more than two syllables use function words, as shown in the next examples:

Positive	Comparative	Superlative
accurate	more accurate	most accurate
accurate	less accurate	least accurate
beautiful	more beautiful	most beautiful
beautiful	less beautiful	least beautiful
interesting	more interesting	most interesting
interesting	less interesting	least interesting

Many adjectives, including *handsome, happy, lovely,* and *proud,* may be compared by either method—for example, *happy, happier, happiest;* or *happy, more happy, most happy.*

A special group of adjectives show comparison by *irregular* forms. That is, their changes in form follow no set rules. Here are some examples:

Positive	Comparative	Superlative
bad	worse	worst
far	farther, further	farthest, furthest
good	better	best
little	littler, less, lesser	littlest, least
many, much	more	most

Although many adjectives show three degrees of comparison, such adjectives as *chief, main,* and *foremost* exist in only one degree and cannot be compared at all. There is a difference of opinion about whether adjectives such as *round, perfect,* and *unique* can be compared. Many persons consider them absolute adjectives that cannot show degree, except in phrases such as *almost round, more nearly perfect,* and *almost completely unique.* However, such comparisons as *more round, more perfect,* and *most unique* have become increasingly common in informal usage.

Classifying adjectives. Adjectives are classified into several types according to their meaning and function.

Descriptive adjectives specify the kind, nature, or condition of the words they modify, as in *When we saw the* fierce *dog, we grew* cautious.

Proper adjectives come from a proper name and are written with a capital letter. Some examples of proper adjectives are: *American flag, Roman numerals,* and *Shakespearean sonnets.*

Interrogative adjectives ask a question, as in Which *car do you mean?* or What *difference does it make?*

Determiners are adjectives that place limits on a noun rather than add description. Several groups of words serve as determiners. They include the articles *a, an,* and *the;* the *demonstrative* adjectives *that, this, these,* and *those;* and the *indefinite* adjectives *all, each, no, some, other,* and *much;* and such numbers as *one box* and *second place.* Some scholars consider determiners to be a separate part of speech.

Usage. The careful use of adjectives can clarify meaning, but too many adjectives in a sentence may confuse a reader or listener. One carefully chosen adjective often can express more information than two or three vague ones.

Sometimes a person may have difficulty in deciding whether to use an adjective or an adverb after certain verbs. If the sentence requires a word to modify the verb, the choice should be an adverb—for example, *Helen sings well,* not *Helen sings good.* If the sentence requires a word following a linking verb to modify the subject, the choice should be an adjective—for example, *I feel bad,* not *I feel badly.* In the sentence *He looked calmly at the judge,* the word *calmly* is an adverb that modifies *looked.* It describes the manner in which the person acted. In the sentence *He looked calm,* the word *calm* is a predicate adjective that modifies *he.* It describes the condition of the subject.

Errors in agreement can be created when such words as *kind, sort,* and *type* are used with the demonstrative adjectives *this* or *that.* In such cases, both the adjective and the noun should be either singular or plural. For example, *I like this kind of motion picture* or *I like these kinds of motion pictures,* but not *I like these kind of motion pictures.* Susan M. Gass

Adjutant, *AJ uh tuhnt,* is the name of two species of large birds in the stork family. They are found in India and Southeast Asia. The *greater adjutant* stands about 5 feet (1.5 meters) high, and the *lesser adjutant* measures up to 4 feet (1.2 meters) tall. Both birds have a white body, and the back and wings are dark gray. The greater adjutant has a long bag of skin that hangs under its bare neck. The bird can puff out this skin and fill it with air. The Indian government protects adjutants because these birds eat dead animals that would otherwise decay and possibly spread diseases. Eric G. Bolen

Scientific classification. Adjutants belong to the stork family, Ciconiidae. The greater adjutant is *Leptoptilos dubius,* and the lesser adjutant is *L. javanicus.*

See also Marabou; Stork.

E. R. Degginger

The adjutant is the largest member of the stork family. It has a long beak and a white body with a gray back and wings.

Adler, Alfred (1870-1937), an Austrian psychiatrist, developed important theories concerning the motivation of human behavior. According to Adler, the major force of all human activity is a striving from a feeling of inferiority toward perfection. Adler at first referred to this force as an *aggressive drive.* He later called the force a *striving for superiority.* Adler termed his school of thought *individual psychology.* Today, it is often referred to as *Adlerian psychology.*

Adler taught that everyone experiences feelings of inferiority and each person strives to overcome such feelings according to a unique set of goals. Every individual, he said, also has a unique way of attempting to achieve the goals. Adler used the term *style of life* for the person's goals and methods of pursuing them. He claimed that the style of life becomes established by the age of 4 or 5. He also believed that an individual's self-image and opinion of the world reflect the person's style of life.

Adler emphasized the importance of social forces in determining behavior. He believed everyone is born with a trait called *social interest,* which enables a person to relate to other people and to place the good of society above their own interests. Many of Adler's ideas have become part of the theory and practice of psychiatry.

Adler was born near Vienna, Austria. He received his M.D. degree from the University of Vienna in 1895. Adler was an eye specialist and a neurologist before becoming a psychiatrist. From 1902 to 1911, he worked with the famous Austrian neurologist and psychoanalyst Sigmund Freud. From 1921 to 1934, Adler established child guidance clinics in Vienna. He trained teachers, worked with parents, and supervised teachers' clinical activities with disturbed children. Adler moved to New York City in 1934. Hannah S. Decker

Adler, Dankmar (1844-1900), was an American architect noted primarily for his association with architect Louis H. Sullivan. The two formed the partnership of Adler & Sullivan in 1883. Together they designed such important structures as the Auditorium Building (1889) in Chicago and the Wainwright Building (1891) in St. Louis. These buildings helped define the influential Chicago School of architecture. The firm's other notable Chicago structures include the Chicago Joint Board Building (1884), the Garrick Theater in the Schiller Building (1892), the Transportation Building (1893) at the World's Columbian Exposition, and the Stock Exchange Building (1894).

In spite of Adler's training as an architect, his responsibilities within the firm seem to have been limited to structure, ventilation, and acoustics, in which he was an expert. Adler was also an excellent business manager. The partnership was dissolved in 1895 following the construction of the Guaranty Building (1895) in Buffalo, New York.

Adler was born near Eisenach, Germany, and immigrated with his family to the United States in 1854. He moved to Chicago in 1861 and served as an engineer in the Union army during the Civil War (1861-1865). Adler returned to Chicago in 1866. Nicholas Adams

Administrator is a person who takes charge of the property of a person who has died. Probate courts appoint administrators to handle the property of a person who leaves no will, or who leaves a will but names no executor. An *executor* is a person who is named in a will to handle property (see Executor). The administrator's duty is to collect the assets of the dead person's estate, pay claims against the estate, and then distribute the balance to the person's heirs and next of kin—or to the *legatees* (beneficiaries) of the will if there is one.

Courts usually name a qualified close relative of the deceased to serve as administrator. In many large cities, officials called *public administrators* manage the estates of dead people who have no relatives. When citizens of another country die while in the United States without leaving a will, their country's consul is usually named to administer the estate. William M. McGovern

See also Probate; Will (document); Heir.

Admiral is the highest rank in the navy of the United States and of many other countries. Most admirals command fleets or specially organized naval units called *task forces* or *task groups.*

There are four basic grades of admiral in the U.S. Navy. They are—from the lowest to the highest grade—rear admiral, vice admiral, admiral, and fleet admiral. A rear admiral wears the insignia of two stars and generally commands a task group. A vice admiral wears three

stars and commands a task force. An admiral, with four stars, commands a fleet. The rank of fleet admiral carries five stars. It was created in 1944 and was held by four heroes of World War II—William F. Halsey, Ernest J. King, William D. Leahy, and Chester W. Nimitz.

The word *admiral* comes from the Arabic term *amir-albahr,* which means "commander of the sea." The title of admiral was introduced into Europe during the Crusades (A.D. 1096–1500's). In the United States, captains were the highest-ranking Navy officers until 1862, when the rank of rear admiral was adopted. David G. Farragut became the first person to hold this rank. He also became the Navy's first vice admiral in 1864 and its first admiral in 1866. In 1899, Congress created the honorary rank of Admiral of the Navy for George Dewey, a hero of the Spanish-American War. Ann Alexander Warren

See also **Flag officer; Rank, Military.**

Admiralty, *AD muhr uhl tee,* is a department of a nation's government that directs naval affairs. For example, the Admiralty Board in the United Kingdom controls the Royal Navy. Beginning in the 1300's, the Lord High Admiral commanded the Royal Navy. In 1708, the Board of Admiralty (now Admiralty Board) assumed control of naval affairs. Its powers are about the same as those of the Department of the Navy in the United States and of the Maritime Command in Canada. The term *admiralty law* applies to a body of laws relating to ships and shipping. It covers wrecks, collisions, and cargo damage. In the United States, district courts hear these cases. See also **Maritime law.** Ann Alexander Warren

Admiralty Islands, *AD muhr uhl tee,* a group of islands in the South Pacific Ocean, are part of the nation of Papua New Guinea. The islands have a population of about 30,500 and cover 800 square miles (2,072 square kilometers). The group includes one large island (Manus), several small, hilly volcanic islands, and about 100 low reef islands (see **New Guinea** [map]). Lorengau, the group's principal town, is on Manus Island.

The first Europeans to reach the island were probably the Dutch navigators Willem Schouten and Jakob le Maire. In 1616, they found the islands inhabited by Melanesians, a dark-skinned people with black, woolly hair. Germany claimed the group in 1884. Australians captured the islands in World War I (1914-1918), and Japan occupied them in 1942, during World War II (1939-1945). In 1944, American and Australian troops recaptured the islands. A naval base was built at Manus and was used to launch the invasion of the Philippine island of Leyte in 1944. The base was later abandoned. David A. M. Lea

Admiralty law. See **Maritime law.**

Adobe, *uh DOH bee,* is the Spanish name for sun-dried bricks, or for a house built with such bricks. A less common type of adobe is made with dampened earth pressed down in building forms similar to those used for poured concrete walks.

People have used adobe to build houses and other structures in desert regions for thousands of years. The ancient Egyptians and Babylonians used adobe.

To make adobe, workers mix sandy clay or loam with water and a small quantity of straw, grass, or similar material. The straw holds the mixture together, giving the bricks greater stability. The mixture is placed in wooden forms that shape it into bricks. Workers remove the forms when the bricks are dry. Then they bake the bricks in the sun from ten days to two weeks.

Adobe houses are common in Mexico and the southwestern part of the United States. Traditional adobe houses are covered with mud. Modern adobe houses are covered with a plasterlike material called *stucco.* Adobe houses are cooler than uninsulated homes made of wood or stone, but adobe is not suitable for use in cold or damp regions. The bricks will crumble if they are exposed to rain or to periods of freezing temperatures followed by thaws. Jack M. Landers

Eric Lindgren

Manus Island, *shown here,* is the largest of the Admiralty Islands. It is covered by a dense tropical forest.

WORLD BOOK photo by Steven Spicer (Jones Metropolitan High School of Business and Commerce, a Chicago Public High School)

During adolescence, relationships with *peers* (people of one's own age) take on great importance. Teen-agers spend much time with their peers in such activities as eating together or chatting after school. The students shown above right attend a high school with a strict dress code.

Adolescent

Adolescent refers to a person who is experiencing the period of development between childhood and adulthood. This period is often called *adolescence.* Many experts in human development believe adolescence begins at about the age of 10. They recognize adolescence as a period of growth with many distinctive features. These features involve changes in the individual's body, thinking abilities, psychological concerns, and place in society.

Human beings, like all mammals, go through a series of physical and biological changes, called *puberty,* that prepares them for sexual reproduction. As a biological phenomenon, therefore, adolescence has always existed as a period in human development. However, adolescence as a separate psychological and social stage is a concept that was developed in industrialized nations during the mid-1800's.

The "invention" of adolescence

Before the 1800's, adults did not make important distinctions among children of different ages. However, new patterns of work and family life came with industrialization in the 1800's. Individuals from age 12 to 16 were greatly affected by these changes. As work shifted away from farming and became less tied to the family, young people needed a new kind of preparation for adulthood. Children in working-class families often took jobs in mines, factories, and mills. Others were apprenticed to craftworkers to learn a trade. Adolescents in middle-class families were expected to attend school, where they were grouped with others of the same age. At school, they could be better educated for a rapidly changing workplace.

By the early 1900's, adolescence in some societies and some social and economic classes had become a lengthy period of preparation for adulthood. During this time, young people remained grouped with people their own age, often referred to as their *peers,* and were economically dependent on adults. This role is still what is expected of adolescents in most societies today.

How society regards adolescence has a tremendous impact on the psychological and social development of individuals. Before the 1800's, the lives of adolescents did not revolve around socializing with their friends. There was no such thing as a "teen culture." Young people seldom felt compelled to take a certain action, adopt certain values, or otherwise conform to be accepted by the group. Today, social pressure from people their own age, known as *peer pressure,* is a major influence on many adolescents.

Before adolescence became defined as a distinct developmental stage, most young people did not struggle to develop a clear sense of self or to sort out what they would become in the future. Most young people had few real choices open to them. Today, psychological experts use the term *identity crisis* to refer to the psychological distress many adolescents feel as they seek a sense of purpose and an acceptable role in the world. Peer pressure, popular culture, and identity crises may seem to make up the core of adolescence, but they are actually consequences of how adolescence is defined today.

Physical development

Puberty is the most obvious sign that an individual has entered adolescence. Technically, puberty refers to the period during which the individual becomes capable of sexual reproduction. More broadly, however, puberty is used as a collective term for all the physical

---

Laurence Steinberg, the contributor of this article, is Professor of Psychology at Temple University and co-author of You and Your Adolescent: A Parent's Guide for Ages 10 to 20.

changes that occur in a growing girl or boy as the individual passes from childhood to adulthood.

The physical changes of adolescence are triggered by *hormones* (chemical substances in the body) that act on specific organs and tissues. In boys, a major change is increased production of the hormone *testosterone,* while girls experience increased production of the hormones called *estrogens.* In both sexes, a rise in growth hormone produces a growth spurt. During this spurt, which lasts two or more years, an individual commonly grows 2 to 4 inches (5 to 10 centimeters) taller per year.

Sexual development. Many of the most dramatic changes of puberty involve sexual development. Internally, adolescents become capable of sexual reproduction. Externally, as secondary sexual characteristics appear, girls and boys begin to look more like mature women and men. The term *secondary sexual characteristics* refers to a variety of physical traits, such as body shape, voice, and facial hair.

Not everyone goes through puberty at the same time or rate. In Western industrialized societies today, the adolescent growth spurt occurs, on average, between the ages of 12 and 14 in boys, and 10 and 12 in girls. But some young people start puberty when they are 8 or 9, and others not until they are in their mid-teens. Generally, girls begin puberty about two years earlier than boys. The duration of puberty also varies greatly, from $1\frac{1}{2}$ to 6 years in girls and from 2 to 5 years in boys.

Adolescent "awkwardness." Because different parts of the body grow at different rates during puberty, many adolescents temporarily look and feel awkward. For many years, psychologists believed that puberty was stressful for young people. According to one theory, changes in hormones made young adolescents moody, irritable, and depressed. We now know that most emotional disturbances in adolescence result from changes in the teen-ager's roles and relationships. Adolescents can minimize difficulties associated with adjusting to puberty by knowing what changes to expect and having healthy attitudes toward them.

The timing of puberty may affect an adolescent's social and emotional development in important ways. Because early-maturing boys and girls appear older physically, people often treat them as if they were more mature psychologically than they are. Early maturers will more likely engage in risky behavior during early adolescence, such as experimentation with drugs, sex, or delinquency. Many psychologists believe these risky actions result from the influence of older teen-agers, who befriend early maturers more often than they befriend younger-looking adolescents.

Because of the emphasis many boys place on athletics, early-maturing boys may have temporary advantages over their peers. As a result, during the first years of adolescence, early-maturing boys tend to be more popular, have higher self-esteem, and have more self-confidence than average- or late-maturing boys.

In contrast, the effects of early maturation on girls are more mixed. Early-maturing girls tend to be more popular with their peers. But they are also more likely to feel awkward and self-conscious, perhaps because they are uncomfortable with the attention, both welcome and unwelcome, their new appearance draws.

Over time, puberty has begun at younger and younger ages. Part of the trend is due to improvements in nutrition and health care. The trend appears to be leveling off, however.

National Archives/Photo Researchers

An adolescent of the past worked long hours in a factory, *shown here.* Before the 1800's, adolescence was not regarded as a separate psychological and social stage of development.

Intellectual development

Compared with children, adolescents begin to think in ways more like adults. Their thinking becomes more advanced, more efficient, and generally more effective. These improvements appear in five chief ways.

(1) An adolescent's thinking is less bound to concrete events than that of a child. Children's thinking focuses on things and events that they can observe directly in the present. Adolescents can better compare what they observe with what they can imagine.

(2) During adolescence, individuals become better able to think about abstract things. Adolescents have an increased interest in relationships, politics, religion, and morality. These topics involve such abstract concepts as loyalty, faith, and fairness.

(3) Adolescents think more often about the process of thinking itself. As a result, they can develop better ways to remember things and to monitor their own thinking.

(4) Adolescents have the ability to think about things in several ways at the same time. Adolescents can give much more complicated answers than children to such questions as "What caused the American Civil War?" Adolescents have more sophisticated, complicated relationships with others because they can better understand other people's feelings. They also understand that social situations can have different interpretations, depending on one's point of view.

(5) Children tend to see things in absolute terms. Adolescents often see things as relative. They are more likely to question statements and less likely to accept "facts" as unquestionably true. This change can be frustrating to parents, who may feel that their adolescent children question everything just for the sake of argument. However, such questioning is normal and helps teen-agers develop individuality and personal convictions.

One by-product of these changing aspects of intellec-

tual development is the tendency for adolescents to become self-conscious and self-absorbed. This tendency is sometimes called *adolescent egocentrism.* Intense self-consciousness sometimes leads teen-agers mistakenly to believe that others are constantly watching and evaluating them. A related problem is an adolescent's incorrect belief that his or her problems are unique. For example, a teen-ager who has just broken up with a girlfriend or boyfriend may say that nobody else could possibly understand what he or she is feeling, even though such breaking up is a common experience.

Psychological development

Identity and self-esteem. As individuals mature, they come to see themselves in more sophisticated, complicated ways. Adolescents can provide complex, abstract psychological descriptions of themselves. As a result, they become more interested in understanding their own personalities and why they behave the way they do. Teen-agers' feelings about themselves may fluctuate, especially during early adolescence. However, self-esteem increases over the course of middle and late adolescence, as individuals gain more confidence.

Some adolescents go through periods when they genuinely wonder what their "real" personality is. Adolescents who have gone through a prolonged identity crisis may feel a stronger sense of identity as a result of taking the time to examine who they are and where they are headed.

Independence and responsibility. During adolescence, individuals gradually move from the dependency of childhood to the independence of adulthood. Older adolescents generally do not rush to their parents whenever they are upset, worried, or need assistance. They solve many problems on their own. In addition, most adolescents have a great deal of emotional energy wrapped up in relationships outside the family. They may feel just as attached to their friends as to their parents. By late adolescence, children see their parents, and interact with them, as people—not just as a mother and father. Unlike younger children, adolescents do not typically see their parents as all-knowing or all-powerful.

Being independent also means being able to make one's own decisions and behave responsibly. In general, decision-making abilities improve over the course of the adolescent years, with gains in being able to handle responsibility continuing into the late years of high school.

During childhood, boys and girls are dependent upon and relate closely to their parents rather than their peers. During early adolescence, conformity to parents begins to decline, while peer pressure and conformity to peers increase. Peer pressure is particularly strong during junior high school and the early years of high school.

Adolescents yield more often to peer pressure when it involves day-to-day social matters, such as styles of dress, tastes in music, and choices among leisure activities. But teen-agers are mainly influenced by their parents and teachers when it comes to long-range questions concerning educational or occupational plans, or decisions involving values, religious beliefs, or ethics.

Becoming independent involves learning how to cope with peer pressure. During middle adolescence, individuals begin to act the way they think is right, rather than trying to impress their friends or please their parents.

Social development

Relationships with peers change in four important ways during the teen-age years: (1) There is a sharp increase in the amount of time adolescents spend with their peers compared to the time they spend with adults or their families. (2) Peer groups function much more often without adult supervision than they do during childhood. (3) In most societies, there is much more contact with peers of the opposite sex. (4) Adolescents tend to move in much larger peer groups than they did in childhood. Crowds tend to dominate the social world of the school.

The increased importance of peers during early adolescence coincides with changes in an individual's need for intimacy. As adolescents begin to share secrets with their friends, a new sense of loyalty and commitment grows between them. An adolescent's discovery that he or she thinks and feels the same way as someone else becomes an important basis of friendship and helps in the development of a sense of identity.

Dating and sex. In industrialized societies, most young people begin dating sometime during early to mid-adolescence. Dating can mean a variety of activities, from gatherings that bring males and females together, to group dates, in which a group of boys and girls go out jointly. There can be casual dating in couples or serious involvement with a boyfriend or girlfriend.

Most adolescents' first experience with sex does not involve another person. Many boys and girls report having sexual fantasies about someone they know or wish they knew. It is also fairly common for adolescents to *masturbate* (handle or rub their sex organs).

By the time many adolescents have reached high school, they have had some experience with intimate sexual contact, such as kissing, caressing, or sexual intercourse. During the 1970's and 1980's, more adolescents became sexually active than in the past and they became sexually active at an earlier age. Surveys in the late 1990's, however, indicated that the trend toward becoming sexually active at an early age might be leveling off. Many individuals and religious groups consider sexual activity outside of marriage to be morally wrong. They also urge adolescents to avoid sexual activity for health reasons.

Family relationships change most about the time of puberty. Conflict can increase between parents and adolescents, and closeness between them diminishes somewhat. Changing adolescent views on family rules and regulations may contribute to increased disagreement between young people and their parents.

Although young people may distance themselves from their parents as they enter adolescence, this period is not normally a time of family stress. Most conflicts take the form of minor arguments over day-to-day issues. In many families, the decline in closeness between parents and children in early adolescence results from the adolescent's increased desire for privacy. In addition, teen-agers and parents may express affection for each other less often. Generally, this distancing is temporary, and family relationships become closer and less

conflict-ridden during middle and late adolescence.

Certain constants remain in family life. Among the most important is an adolescent's need for parents who are both nurturing and demanding. This combination of warmth and strictness is associated with healthy psychological development. Children raised by loving parents who maintain clear and constant personal and social standards are more likely to have good feelings about themselves than children brought up by harsh or lax parents. Adolescents raised with both warmth and firmness are more likely to excel in school, to have close and satisfying relationships with others, and to avoid trouble with drugs and delinquency.

Special problems and challenges

Adjusting to school life. A young person's move from elementary school to middle school or junior high school can be difficult. In elementary school, the child had a single homeroom teacher who knew him or her personally. In middle school or junior high, the child usually has a different teacher for each subject. In elementary school, children are rewarded for trying hard. In middle or junior high school, grades are based more on performance than on effort. In elementary school, children work under close supervision all day. In middle school or junior high, young people must learn to work more independently.

For such reasons, many students are temporarily disoriented during the transition between schools. Their self-esteem falters, and their grades may drop off slightly. Their interest in school activities declines. They may feel anonymous, isolated, and vulnerable. Parents can help by talking to the child before school begins about the differences he or she will experience.

Alcohol and drug abuse. Many adolescents in industrialized countries experiment with alcohol, tobacco, and marijuana. Adolescents may experiment with such substances because of a desire to fit in with their friends. Many adolescents see smoking, drinking, and using drugs as a key to popularity. Other reasons adolescents experiment with drugs and alcohol include boredom, and a desire to feel grown-up—that is, they see drugs as a way to prove they are adults and no longer under adult control.

Young people who abuse drugs and alcohol are more likely to experience problems at school, to suffer from psychological distress and depression, to have unsafe sex, and to become involved in dangerous activities. Alcohol and drugs often contribute to automobile accidents, the leading cause of death among American teenagers. Adolescent substance abusers also expose themselves to long-term health risks that result from drug addiction or dependency.

Pregnancy. Some young women become pregnant before the end of adolescence. Adults can help adolescents prevent unwanted pregnancies. For example, parents and teachers can provide sex education to instruct young people in how to deal with their sexual feelings before they become sexually active. Adults also can make adolescents feel more comfortable about discussing sexual matters so that young people will examine their own behavior seriously and thoughtfully.

Establishing a sexual identity. Normal developmental tasks of adolescence include learning to think of oneself as a sexual being, to deal with sexual feelings, and to enjoy a new kind of closeness with another person. Part of this involves developing a sexual identity. Sexual identity includes *sexual orientation*—that is, whether a person is sexually attracted to the opposite sex or the same sex. People who are primarily attracted to members of their own sex are called *homosexual*, *gay*, or, if they are women, *lesbian*. People who are attracted to the opposite sex are called *heterosexual* or *straight*. No one factor determines sexual orientation.

© Bob Higbee, Berg & Associates

Dating normally begins during adolescence. Learning to enjoy a new kind of closeness with another person is a normal developmental task of this period of life, as well as learning to think of oneself as a sexual being and to deal with sexual feelings.

At some time, almost all young adolescents worry that they might be homosexual. At the age when children enter puberty, they still spend most of their time with members of the same sex. As a result, many adolescents begin to experience sexual feelings before they have much contact with the opposite sex. This does not mean that all of these young adolescents have homosexual desires. Their sexual development is just ahead of their social development.

Unfavorable attitudes toward homosexuality may cause significant psychological distress for adolescents who experience gay and lesbian feelings, especially if they encounter hostility from those around them. The psychological tasks of adolescence, such as developing a sense of identity, present great challenges for all teenagers. These challenges may be intensified for those adolescents attracted to members of the same sex. They may have to resolve these issues without the social support available to their heterosexual peers.

Eating disorders. Some adolescents, especially females, become so concerned about weight control that they take drastic and dangerous measures to remain

© Billy E. Barnes, Photo Edit

Conflicts between adolescents and their parents can arise because adolescents are more likely than children to question what they are told and more likely to disagree with family rules.

thin. Some overeat and then force themselves to vomit to avoid gaining weight. This pattern is associated with an eating disorder called *bulimia*. Young women with a disorder called *anorexia nervosa* actually starve themselves to keep their weight down. Adolescents with eating disorders have an extremely disturbed body image. They see themselves as overweight when they are actually underweight. Bulimia and anorexia nervosa are rare before the age of 10. It was once believed that eating disorders were more common in North America and Western Europe than in other parts of the world, and were more common among the prosperous and well educated. However, research in the late 1990's found these disorders to be common among all social and economic levels, and in many countries throughout the world.

Although the incidence of anorexia and bulimia is small, many adolescents, especially females, remain unhappy with their body shape or weight. Many girls whose weight is normal by medical and health standards believe they are overweight. A majority of adolescent girls report that they would like to be thinner. Most believe that being thinner would make them happier, more successful, and more popular.

Delinquency. Violations of the law are far more common among adolescents and young adults than in any other age group. Violent crimes and crimes against property peak during high school.

Violent crime is a serious concern to youths as well as to adults. Adolescents are the age group most likely to become victims of such crimes as theft, robbery, rape, and assault. However, adolescents may also commit such violent crimes. Delinquents who repeatedly commit serious crimes typically come from disrupted or badly functioning families, and they frequently abuse alcohol or drugs. Hostile, neglectful, or unfit parents may mistreat children and fail to instill in them proper standards of behavior or the psychological foundations of self-control.

Risk taking. Many adolescent health problems result from behaviors that can be prevented. These behaviors include substance abuse, reckless driving, unprotected sex, and violence. One particular concern is sexually transmitted diseases, such as AIDS, among teen-agers. Some people mistakenly consider AIDS a homosexual disease, but the virus can be transmitted from male to female or female to male. The virus is also transmitted through needles and syringes that are used in taking drugs. It may even be spread by tattooing or body piercing if the instruments were previously used on an infected person.

Suicide. The suicide rate among teen-agers has risen dramatically since the mid-1900's. Four factors in particular place an adolescent at risk for a suicide attempt: (1) suffering from low self-esteem or an emotional problem, such as depression; (2) being under stress, especially in school or because of a romantic relationship; (3) experiencing family disruption or family conflict; and (4) having a history of suicide in the family or a friend who has committed suicide.

Any threat of suicide demands immediate professional attention. Anyone who suspects an adolescent is considering suicide should immediately call a suicide hot line or the emergency room of a local hospital.

Planning for the future

Career planning is part of the identity development process during adolescence. Occupational plans develop in stages. Prior to adolescence, children express career interests that are often little more than fantasies and have little bearing on the plans they eventually make. In adolescence, individuals begin to develop self-concepts and ideas about work that will guide them in their educational and occupational decisions. Although adolescents may not settle on a particular career at this point, they do begin to narrow their choices according to their interests, values, and abilities.

One problem all young people face in making career plans is obtaining accurate information about the labor market and the best ways of pursuing positions in various fields. One goal of career education is to help adolescents make more informed choices about their careers and to free them from misinformation that inhibits their choices. For a discussion of how to choose and plan a career, see the **Careers** article.

Education is essential today for any person who wants a well-paying job with a promising future. Young people need at least a high school education to compete in the job market. Those who want to go into a craft or trade usually need a two-year course of college study.

Most of the better jobs go to individuals with at least some college education. However, getting a job is not the only reason for going to college. College plays a critical role in a young person's psychological development. College not only provides occupational advantages but also affects where individuals will live, whom they will marry, who their lifelong friends will be, and, most important, who they become. Adonis, *uh DAHN ihs,* was a handsome youth in Greek mythology. Adonis's beauty attracted Aphrodite, the goddess of love. According to one myth, Aphrodite warned him of the dangers of hunting. But Adonis did not heed her advice and was killed by a boar, or by Hephaestus, Aphrodite's jealous husband, disguised as a boar. A flower called the *anemone* sprang either from Adonis's blood or from Aphrodite's tears at his death.

Marble sculpture (mid-1600's) by Dionisio Mazzuoli; Hermitage museum, St. Petersburg (Bridgeman Art Library)

Adonis was a handsome young man in Greek mythology. According to one myth, he was killed by a boar he was hunting.

According to another myth, Aphrodite placed the infant Adonis in a chest and gave it to Persephone, the queen of the underworld, for safekeeping. Persephone became enchanted with the youth and wanted to keep him. To settle the quarrel between the goddesses, Zeus, king of the gods, ruled that Adonis would spend part of the year with Aphrodite and part of the year with Persephone. When Adonis stayed with Aphrodite on earth, plants and crops flourished. During his time in the underworld, vegetation died. The Greeks used this myth to explain why the seasons changed. They honored Adonis in ceremonies and by cultivating plants that grew and died quickly. Nancy Felson

Adonis, *uh DAHN ihs,* is the name of a group of 20 species of plants that grow wild in Europe and Asia.

WORLD BOOK illustration by Christabel King

The autumn Adonis has bright red flowers. It grows wild in Europe and Asia but is sometimes cultivated in gardens.

They are sometimes cultivated in gardens in North America. Some types of Adonis plants may grow 1 foot (30 centimeters) high. The *autumn Adonis,* also called *pheasant's-eye,* has flowers with bright red petals. The *spring Adonis* has flowers with gold petals.

Kenneth A. Nicely

Scientific classification. Adonis plants are members of the crowfoot family, Ranunculaceae. The scientific name for the autumn Adonis is *Adonis annua.* The spring Adonis is *A. vernalis.*

Adoption is a legal process by which people take as their own son or daughter a person not born to them. Most *adoptees* (adopted persons) are adopted when they are children. Adoptees are entitled to the same privileges as children born to a parent or parents, including the right to inherit property. This article chiefly discusses the adoption of children.

Many adoptions occur partly out of a need to find permanent, loving families for babies who are the result of unwanted pregnancies. Numerous other adoptions involve foster children who need permanent homes after being legally separated from their birth parents. Many adults adopt children because they are, for medical reasons, unable to become birth parents, or because they choose not to become birth parents. Surveys show that most adoptions work out well and that most adopted children develop normally.

In the United States, there are about 2 million adopted children under the age of 18. Each year, approximately 150,000 children are adopted, two-thirds of them by their relatives. In Canada, about 15,000 children are adopted every year.

The adoption process is similar in the United States and Canada. In the United States, licensed agencies arrange more than half of all adoptions by nonrelatives. These agencies are either privately funded or public and tax-supported. In Canada, provincial agencies handle most adoptions by nonrelatives. Agency adoptions involve three steps: (1) the legal separation of a child from the birth parents, (2) the transfer of custody to a qualified adoption agency, and (3) the transfer of parental rights and responsibilities to the adoptive parents.

When a couple applies to an adoption agency, the agency assigns them a caseworker. The caseworker obtains information about the couple's health and emotional maturity and answers their questions about the physical and emotional development of the child they want to adopt. The caseworker also makes sure the couple has a stable relationship and can afford to support the child. This process is often called the *home study.*

In some cases, a single person applies to an agency to adopt a child. Although most agencies choose couples over single applicants, agencies sometimes place children who have special needs with single individuals when two-parent homes cannot be found. Children with special needs include older, disabled, or emotionally disturbed children; minorities; and brothers and sisters who need to be adopted together. In the United States, adoptive parents have not been found for more than 100,000 children with special needs. Most of these children live with *foster parents* (see **Foster care**).

Some people adopt a child without the services of an agency. In many cases, physicians and lawyers put birth parents in touch with couples wishing to adopt. These adoptions are called *private,* or *independent,* adoptions. Many private adoptions do not involve a thorough home study. Private adoptions are illegal in some states.

In most states and provinces, adoptions do not become legal until children have lived in the home of their adoptive parents for 6 to 12 months. A lawyer then prepares a formal request for adoption. The adoptive parents submit the request to the proper court. If the court approves the request, the adoption becomes legal.

International adoptions. Most adoptive parents adopt children who were born in the country in which the adoptive parents live. Since the 1960's, however, the number of people waiting to adopt children in the United States has risen while the number of available infants in the country has declined. Therefore, some people adopt children from other countries. In most U.S. states, many of these *international,* or *intercountry,* adoptions are handled by state agencies. Other states rely only on independent, voluntary agencies to connect couples with foreign babies needing adoption.

The United Nations has established guidelines concerning the rights of foreign adoptees. These guidelines recommend using authorized adoption agencies that can provide the same protection that children receive in national adoptions. According to the guidelines, the child should have an official name, nationality, and legal guardian at every stage of the adoption process.

Interracial adoptions are those in which a couple or person considered to be of one race adopts someone considered to belong to another race or to be of mixed race. Most international adoptions are also interracial adoptions.

Black market adoptions. The scarcity of adoptable infants has led, in some cases, to the buying and selling of babies. Such transactions, known as black market adoptions, are against the law.

Rights of adoptive parents and adoptees. Most states and provinces keep adoption records secret once a child is adopted. The state or province issues a new birth certificate showing only the names of the adoptive parents. However, many adopted persons want to know more about their backgrounds. Some organizations concerned about the rights of adopted persons have

proposed that nonidentifying information about the child be given to the adoptive parents. Such information would not reveal the identity of the birth parents but might include their medical and ethnic histories. In a small number of states, adopted adults have a legal right to see their original birth certificates.

Adopted persons and birth parents may decide that they want to contact one another. A number of states and provinces maintain registries to aid these people. However, adopted children may not register until they reach adulthood. In addition, both the adopted person and the birth parents must register before contact may be established.

Some groups favor *open adoptions.* In an open adoption, the birth parent or parents meet the adoptive parents and participate in the adoption process. The birth parents give up their basic parental rights but keep the right to remain in contact with the child. The birth parents also have the right to know where the child lives and to keep informed about the child's well-being.

History. People have been adopting children for thousands of years. In ancient times, a childless person often adopted an individual in order to have a legal heir. Adoptions were common among the ancient Greeks, Romans, Babylonians, and Assyrians. One of the first written law codes, the Babylonian Code of Hammurabi (1700's B.C.), includes a lengthy section about adoption. In the United States, the first adoption law was passed in Massachusetts in 1851. Sheila Macmanus

Adrenal gland, *uh DREE nuhl,* is a small, pyramid-shaped organ that secretes many important hormones. The body has two adrenal glands, one on top of each kidney. The adrenals, also called *suprarenals,* measure about 2 inches (5 centimeters) each in diameter. Each adrenal gland consists of a *medulla* (inner core) and a *cortex* (outer shell).

The adrenal medulla is controlled by the nervous system. Nerve signals stimulate the medulla to secrete *epinephrine* (also called *adrenalin)* and norepinephrine (also called *noradrenalin)* into the blood. These hormones help the body adjust to sudden stress. For example, they increase the rate and strength of the heartbeat, raise the blood pressure, and speed up the body's energy-producing processes.

The adrenal cortex secretes many hormones, some of which are essential to life. These hormones, called *corticosteroids,* belong to three main groups—(1) glucocorticoids, (2) mineralocorticoids, and (3) sex hormones.

Glucocorticoids regulate the use of digested foods and help the body adapt to stress. The most important glucocorticoid is *cortisol,* also called *hydrocortisone.* The secretion of the glucocorticoids is controlled by *adrenocorticotropic hormone* (ACTH). ACTH is produced by the *pituitary gland,* a small organ near the base of the brain. Physicians use cortisol, and synthetic compounds that resemble it, to control inflammation.

Mineralocorticoids regulate the excretion of sodium and potassium by the kidneys. *Aldosterone* is the most important mineralocorticoid. *Renin,* a hormone secreted by the kidneys, controls the production of aldosterone. Overproduction of aldosterone causes high blood pressure in some people.

WORLD BOOK illustration by Leonard Morgan

The adrenal glands are important hormone-producing organs that lie atop the kidneys. As shown in the circle, each gland consists of two parts, an outer *cortex* and an inner *medulla.*

The adrenal glands produce only small amounts of sex hormones, chiefly the male sex hormones called *androgens.* The adrenal androgens help regulate the development of pubic hair and other early sexual characteristics in both males and females during the period just prior to puberty. Adrian, Roman emperor. See Hadrian.

Adrian IV (about 1110-1159) was the only English pope. He was elected pope in 1154. The city of Rome was in revolt against the papacy at the time of his election. Adrian placed Rome under a religious ban. With the cooperation of the Holy Roman Emperor Frederick I, Adrian regained control of the city. Adrian made great claims for papal authority, and his policies led to a split between the empire and the papacy after his death.

At the imperial Diet of Besançon in 1157, Adrian sent a letter to Frederick in which he claimed that he had bestowed the empire on Frederick as a fief of the papacy. The letter caused a great uproar because it implied that the emperor was subordinate to the pope. Adrian explained that the translation of an ambiguous word led to the misunderstanding, and that he had only meant that the emperor had received "gifts" from the pope. The exchange destroyed the relationship between the pope and the emperor. The next year, at the Diet of Roncaglia, Frederick declared imperial authority over all of northern Italy. Adrian threatened to excommunicate Frederick if he did not withdraw his claims. But the pope died soon after the confrontation.

Adrian was born near St. Albans. His given and family name was Nicholas Breakspear. Kenneth Pennington

Adrianople. See Edirne.

Adriatic Sea, *AY dree AT ihk,* is an extension of the Mediterranean Sea. It lies east of Italy and separates Italy from Croatia, Yugoslavia, and Albania. The Strait of Otranto joins the Adriatic to the Ionian Sea, another arm of the Mediterranean.

The Adriatic Sea is about 480 miles (772 kilometers) long. It has an average width of 100 miles (160 kilometers) and an area of about 60,000 square miles (160,000 square kilometers).

The Po and Adige rivers empty into the Adriatic. The Dalmatian coast, in Croatia, and the Albanian coast are rocky and dotted with islands. The Italian coast is low and flat.

Adriatic Sea

WORLD BOOK map

Both the Italian and Croatian coasts are popular tourist regions. They are noted for their scenery and mild climate. Major port and resort cities on the Adriatic include Trieste, Venice, Ancona, Pescara, and Bari in Italy; and Rijeka, Split, and Dubrovnik in Croatia. Ferry services connect Italian ports on the western coast of the Adriatic Sea with ports on the eastern coast.

Industry and other factors have polluted many areas of the Adriatic. Navigation in the Adriatic is hazardous in winter due to sudden storms. The sea was named for the city of Adria in Italy, once an important Roman port.

Adsorption. See Absorption and adsorption.

Adult education is instruction for men and women who no longer go to school full time. It is also called *continuing education* or *recurrent education.* Adult education includes classes, correspondence courses, discussion groups, lectures, reading programs, and other organized learning activities. In the United States, about 21 million men and women—more than an eighth of the adult American population—take part in some form of adult education.

Men and women enroll in adult education activities for a variety of reasons. Many take part to improve their job skills—to get new jobs or to advance in the ones they have. Some people want to learn such skills as pottery making or speed reading to use in their leisure time. Others participate simply for the joy of learning. Many of these people study such subjects as art, literature, and philosophy. Still other adults attend classes to meet people and make new friends.

Adult education differs in several ways from the education of children. Adults have more experience and knowledge than children do, and teachers plan the instruction accordingly. For example, a teacher might use more group discussions with a class of adults. Most children receive free schooling, but most adults pay for much or all of their instruction. As a result, adult education must provide programs that adults want to buy.

Sources of adult education

The chief sources of adult education are (1) public schools, (2) colleges and universities, (3) proprietary schools, and (4) the government. Many businesses, churches, libraries, museums, park systems, and other organizations also provide adult education programs.

Two major testing programs enable adults to take examinations to earn credit for the equivalent of a high school or college education. These programs are the General Educational Development Test (GED) and the College Level Examination Program (CLEP).

The GED is administered by the departments of education of all the 50 states and of several Canadian provinces. Adults who pass the test receive a *high school equivalency certificate.* Many employers, colleges, and universities accept a GED certificate as the equivalent of a high school diploma. The CLEP enables adults to earn credits that can be applied toward a college degree. The Educational Testing Service, a private agency, administers this program.

WORLD BOOK photo by Dan Miller

Adult education includes courses on a wide variety of subjects. These students in a community college are listening to an instructor lecturing on the history of computers.

Public schools hold adult classes at night in the same buildings used by children during the day. Some schools also offer daytime classes for adults.

Colleges and universities have special programs for adults both on and off the campus. *Extension courses* are provided for people who cannot attend college during regular school hours. Many extension courses do not lead toward a degree. Many are held evenings or weekends, and others are offered by mail or on TV.

Proprietary schools operate like businesses—to make a profit for the owners. Most proprietary schools teach vocational skills for such positions as those of beauty operator, computer programmer, dental assistant, or secretary. Some offer correspondence courses.

The government sponsors a number of adult-education programs. For example, the Department of Agriculture provides training in farming and homemaking for adults in rural areas. The Department of Defense operates a program called the Defense Activity for Non-Traditional Education Support (DANTES). This program furnishes information on correspondence courses and other educational services for men and women in the armed forces. DANTES also enables these men and women to receive high school and college credit by passing examinations, whether or not they take courses. The Department of Education provides funds for instruction in reading, writing, and mathematics up to the eighth-grade level for undereducated adults under the Adult Education Act.

Other sources of adult education include libraries and museums. These institutions offer both individual and group educational programs. Such organizations as the League of Women Voters, the Young Men's Christian Association (YMCA), and the Young Women's Christian Association (YWCA) offer many adult classes. Labor unions provide educational opportunities for their members, and many business companies make schooling and on-the-job training available for employees.

WORLD BOOK photo by Dan Miller

An automotive class for women teaches female car owners to take care of cars and make minor repairs. Such courses help people save money by servicing their cars themselves.

History

The colonial period. Apprenticeship was one of the earliest forms of adult education in the American Colonies. Under this system, a person learned an art or trade by working under a skilled master for a period of time. Many apprenticeship agreements required the master to teach the apprentice to read and write.

In 1727, the American statesman Benjamin Franklin founded one of the first adult-education organizations, a group called the Junto. It met weekly to discuss philosophy, politics, and other topics. In 1731, Franklin organized another means of educating adults, the first subscription library in the colonies. Members of the library paid dues, which entitled them to borrow books. The library used the dues to buy books.

During the 1800's, a wide variety of adult-education institutions developed. Some of the most important of these institutions were study groups called *lyceums*. The members of a lyceum attended debates and lectures and held discussions. Josiah Holbrook, an educator, organized the first lyceum in 1826 in Millbury, Massachusetts. The lyceum movement grew rapidly, and by 1835, more than 3,000 lyceums belonged to the National American Lyceum. This national organization was dissolved in 1839. However, a large number of local lyceums continued to hold regular meetings.

Another important educational movement was the *chautauqua* (pronounced *shuh TAW kwuh)* movement. In 1874, John H. Vincent, a clergyman, and Lewis Miller, a businessman, established a summer school for Sunday school teachers in Chautauqua, New York, near Jamestown. This school, which still exists, soon added other summer programs and a correspondence school. Related institutions, called chautauquas, were later founded in other parts of the country. The word *chautauqua* also referred to traveling groups that went from town to town presenting lectures and entertainment.

In 1891, the educator William Rainey Harper became the first president of the University of Chicago. He established an extension division there, and many other universities soon started their own adult programs.

In the 1900's, the government began to take an increasingly important role in adult education. The Smith-Lever Act of 1914 provided federal funds for instruction in farming and home economics. The Smith-Hughes Act of 1917 financed vocational training.

During the Great Depression of the 1930's, the government sponsored adult-education projects to create jobs for unemployed teachers. These programs were run by the Works Progress Administration (WPA), later called the Work Projects Administration.

After World War II ended in 1945, the government provided funds for veterans to go to school. This program, called the GI Bill of Rights, contributed to the growth of many colleges and universities. It also led to the development of many proprietary schools where veterans could get vocational training.

The Manpower Development and Training Act of 1962 and the Economic Opportunity Act of 1964 furnished federal funds to train unemployed adults. The 1964 act also set up the Adult Basic Education program.

Today, a number of professional associations promote education for adults. One, the Adult Education As-

sociation of the United States of America (AEA/ USA), includes adult-education directors, university professors, and others in adult education. The National Association for Public Continuing and Adult Education is an organization for adult educators in public schools. The American Society for Training and Development has members who are adult educators in business and industry. The National University Continuing Education Association (NUCEA) helps coordinate credit and noncredit adult education programs at the university level.

During the 1970's, many schools became *community schools,* which serve everyone in the community—adults as well as children. Another trend involved *recurrent education* to help adults keep up with the continual new developments in their fields. A high school or college diploma no longer meant the end of a person's education. Five years after graduating from school, an engineer might find that half of what he or she had learned was out of date. Large numbers of men and women began to regard learning as a lifelong activity.

Advent, *AD vehnt,* is the season that marks the beginning of the Christian church year. For most Christians, it starts on the Sunday nearest St. Andrew's Day (November 30) and continues until Christmas Eve (December 24). The term comes from the Latin word *adventus,* which means *coming* or *arrival.* The season is thus one of preparation for the celebration of the feast of the Nativity of Jesus Christ on Christmas Day. See **Christmas** (Religious practices; picture).

Beginning in the 500's, the Advent season was marked by a spirit of penitence, and it lasted as long as six weeks. Under the influence of the church in Rome, the season was gradually reduced to four weeks. The season in modern times has taken on a spirit of somber yet joyful preparation for the Advent of Christ, both in His birth in Bethlehem and on Judgment Day. During Advent, many members of the clergy wear vestments of royal purple or royal blue. David G. Truemper

Adventists, *AD vehn tihsts,* are members of religious groups that stress the doctrine of the *Second Coming.* That is, they believe that Jesus Christ may return to the earth at any moment.

Such questions as when, where, and how Jesus would return have excited the curiosity of Christians. Interest was particularly high during the early 1800's. William Miller, a Baptist minister in Low Hampton, New York, was one of many students of the Bible who tried to find the answers. For years, Miller studied the prophecies recorded in the Old Testament Book of Daniel and the New Testament Book of Revelation. After many calculations, he announced in 1831 that the Second Advent would occur in 1843 or 1844. Thousands of people believed him, and some sold their possessions. His followers, called *Millerites,* waited for the coming of Christ and the end of the world.

When the world did not end in 1844, many of Miller's followers were bitterly disappointed. They abandoned his movement to form new ones. The largest one—the Seventh-day Adventist Church—emerged about the time of the American Civil War. This group also stressed the doctrine of the Second Coming. But it avoided Miller's inclination to predict the specific time of Jesus's return.

The Seventh-day Adventists believe the body is the temple of the Holy Spirit. They abstain from anything that might affect bodily health, including tobacco, alcohol, tea, and coffee. The Adventists conduct an extensive missionary program because they believe the Second Coming cannot take place until all nations have heard the Gospel. Charles H. Lippy

Adverb is a part of speech that adds meaning to a verb, an adjective, or another adverb. Adverbs may be single words *(quickly),* phrases *(in the morning),* or clauses *(if the meeting continues).*

A speaker or writer uses adverbs to add detail by describing *how, when, where,* or *why* something happens. For example, *My brother crawled* becomes more specific if adverbs are added: *After the accident, my brother crawled painfully from the car.* The adverbs modify the verb *crawled. After the accident* is an adverbial phrase that tells *when.* The adverb *painfully* describes *how,* and the adverbial phrase *from the car* shows *where.*

Classifying adverbs

Adverbs can be distinguished on the basis of their use or function as simple adverbs, sentence modifiers, conjunctive adverbs, interrogative adverbs, intensifiers, adverbial equivalents, or parts of verbs in verb-adverb combinations.

Simple adverbs are single words. Most of them end in *-ly,* as in *certainly* and *deeply.* Some simple adverbs do not have an *-ly* ending. They include *above, ahead, down, too,* and *well.*

A few simple adverbs may be used either as adverbs or as adjectives. They include *better, early, fast, much, more,* and *late.* Another group of adverbs has two accepted forms: *close, closely; cheap, cheaply; slow, slowly; even, evenly; deep, deeply; tight, tightly; loud, loudly.* The *-ly* form is preferred in formal usage.

Not all words that end in *-ly* are adverbs. For example, *lovely* and *jolly* are adjectives.

Sentence modifiers are adverbs that modify the whole action of a sentence or clause rather than a single word in it. They often appear at the beginning of a sentence. For example:

Usually *we have dinner on the patio.*
As I recall, *nobody asked any questions.*
Yesterday *I went to a ball game.*

Conjunctive adverbs serve a double purpose. They modify, often as sentence modifiers, but they also serve as *structure* words—words that connect one part of a sentence to another.

You have made a few payments; however, *we must ask you to send checks regularly.*

The adverb *however* connects the two clauses as a conjunction. It also modifies the final clause. Other words commonly used as conjunctive adverbs include *therefore, still, otherwise, also, moreover, nevertheless,* and *yet.* Phrases that are frequently used as conjunctive adverbs include *for example, that is, on the other hand,* and *in conclusion.*

Interrogative adverbs introduce a question: When *did he live*? Where *is the milk*? How *are you*? The most common interrogative adverbs are *how, when, where,* and *why.*

Intensifiers add emphasis to the words they modify. Examples include *very* proud, *extremely* quiet, *quite* concerned, and *too* loud.

Adverbial equivalents are words that are not adverbs but function as adverbs in certain cases. In the sentence *He went home,* the noun *home* serves as an adverb. It modifies the verb *went,* and tells *where.*

Verb-adverb combinations are formed by verbs plus such words as *to, up, off,* or *on.* These words often serve as adverbs or as prepositions. The use of verb-adverb combinations and other adverbial expressions may be seen in the following sentences:

Mary looked up *every new word.*
Mary looked up.
Mary looked up *the old mine shaft.*

In the first sentence, *up* combines with *looked* to function as a single verb, *looked up.* The object of the verb is *every new word.* In the second sentence, *up* is simply an adverb modifying *looked.* In the third, the phrase *up the old mine shaft* modifies the verb *looked.*

Position of adverbs

An adverb can occupy a number of positions in a sentence:

Slowly *she walked off the stage.*
She walked slowly *off the stage.*
She walked off the stage slowly.

In these three sentences, the position of the adverb changes the emphasis but not the overall meaning. However, the placement of certain adverbs can change both the emphasis and the meaning of a sentence. The following three sentences show how the meaning changes with the position of the adverb *only:*

Only *my brother asked to see the gift.*
My brother only *asked to see the gift.*
My brother asked to see only *the gift.*

Other adverbs whose placement can affect the emphasis and meaning of a sentence include *almost, ever, hardly, just, merely, nearly, quite,* and *scarcely.*

Usage

Adverb-adjective confusion. Through usage, certain words have been established as only adverbs and others as only adjectives. Confusion between some of these adjectives and adverbs is common because they are similar in form. The following words often cause trouble:

Adjectives	Adverbs
good (kind, agreeable, (satisfactory)	well (satisfactory), in a desirable way)
real (authentic, genuine)	really (actually)
sure (firm, secure)	surely (certainly)
some (in an indefinite amount)	somewhat (to a certain extent)

Consider the use of adverbs in the following three sentences:

He was surely (*not* sure) *afraid of his mother.*
It was a really (*not* real) *good game.*
He did very well (*not* good) *on his first test.*

Confusion between adverb and adjective is common after linking verbs (some form of the verb *to be* or verbs like *feel, seem, hear,* or *smell*). A linking verb should be followed by an adjective modifying the subject, not an adverb. But the adverb form may be used to modify the verb. For example:

He felt bad (*not* badly) *because he had played so* poorly (*not* poor).

The adjective *bad,* modifying *he,* appears after *felt.* But *poorly,* the adverb, is used to modify *played.*

The use of the adjective *most* in place of the adverb *almost* appears frequently in informal usage. However, the substitution should be avoided in formal writing. For example:

Almost all the elephants died, not *Most all the elephants died.*

Unnecessary adverbs often clutter and confuse a sentence. Usually a single specific verb can replace an adverb and sharpen expression. *Hurried* is preferable to *moved quickly,* and *grasped* is better than *took eagerly.* Such adverbs as *hardly, barely,* and *scarcely* carry a negative meaning. Using the adverb *not* with these words is unnecessary and confusing:

The family had scarcely enough to eat, not *The family did not have scarcely enough to eat.*
I can hardly remember the incident, not *I cannot hardly remember the incident.*

Unnecessary adverbs also may merely repeat and confuse the meaning of the words that they modify. For example:

The old man reverted (*not* reverted back) *to the days of his childhood.*
He advanced (*not* advanced forward) *to his position in the line.*
This (*not* this here) *book has more pictures than that* (*not* that there) *one.*

Adverbs that split an infinitive. An infinitive is the base part of a verb, such as *go* or *see.* It is often used with the word *to,* as in *to go* or *to see. Splitting an infinitive* means placing one or more words between *to* and the verb form, as in *to quickly go* or *to readily see.*

Splitting an infinitive with an adverb is a matter of style rather than correct grammar. It sometimes results in an awkward expression:

He promised to *faithfully and cheerfully* work *with his teacher.*

In this example, the placement of the words *faithfully and cheerfully* splits the infinitive *to work.* The sentence would be easier to understand if the adverbs did not split the infinitive:

He promised to work *faithfully and cheerfully with his teacher.*

In other cases, however, splitting the infinitive may be the only way to get the special emphasis and meaning a writer wants. For example:

I prefer to *actually* see *a play, not just read it.*

Placing *actually* in any other position would alter the meaning of the sentence. William F. Irmscher

Advertising messages promote a wide variety of products, services, and ideas in nearly all the world's countries. The streets of the Ginza district of Tokyo, *shown here,* are lined with brightly colored signs and displays that advertise specific brands of automobiles, beverages, and other goods.

Advertising

Advertising is a message designed to promote a product, a service, or an idea. In everyday life, people come into contact with many kinds of advertising. Printed advertisements make up a large part of newspapers and magazines. Poster ads appear in many buses, subways, and trains. Neon signs along downtown streets flash advertisements. Billboards dot the roadsides. Commercials interrupt TV and radio programs. Advertisements appear on many sites on the World Wide Web.

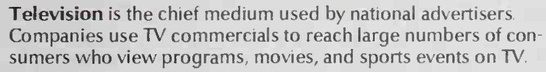
The purpose of most advertising is to sell products or services. Manufacturers advertise to try to persuade people to buy their products. Large business firms also use advertising to create a favorable "image" of their company. Local businesses use it to gain new customers and increase sales. Advertising thus plays a key role in the competition among businesses for the consumer's dollar. In many businesses, the volume of sales depends largely on the amount of advertising done.

Advertising is also used by individuals, political parties and candidates, social organizations, special-interest groups, and the government. Many people advertise in newspapers to sell used cars, homes, or other property. Political parties and candidates use advertising to try to win votes. Social organizations and special-interest groups often advertise to promote a cause or to influence the way people think or act. For example, the Partnership for a Drug-Free America sponsors ads designed to discourage people from using illegal drugs. The United States government uses advertising chiefly to recruit volunteers for the armed forces.

Advertising is a multibillion-dollar industry. More than $200 billion is spent on advertising and advertising-related activities in the United States each year. About $400 billion is spent on advertising in other countries.

Advertising is common in almost all countries. In many countries, however, advertising is more restricted than it is in the United States. In most of the countries of Western Europe, for example, the governments limit the amount of advertising that appears on television. In addition, these governments make greater use of advertising for social, political, and educational purposes.

This article deals chiefly with advertising in the United States. It mainly discusses advertising by business and industrial organizations. But much of the material applies to advertising by other groups as well.



Bonnie B. Reece, the contributor of this article, is Associate Professor of Advertising at Michigan State University.

Ways of advertising

Advertising reaches people through various forms of mass communication. These *media* include newspapers,

Outdoor advertising is effective in communicating brief messages to large numbers of people. Some companies place advertisements on airships called *blimps,* which then fly over highly populated areas and popular events.

magazines, television, and radio. Advertisers buy *space* in newspapers and magazines to publish their ads. They buy *time* on television and radio to broadcast their commercials. National advertisers, such as automobile makers and fast-food restaurants, use the media to reach consumers throughout large parts of the country or all of it. Local advertisers, such as department stores and supermarkets, use the media to reach consumers within a city or town.

The chief advertising media in the United States are (1) television, (2) newspapers, (3) direct mail, (4) radio, (5) magazines, and (6) outdoor signs. Newspapers and television each receive between 20 and 25 percent of the money spent on advertising. A chart in this article shows the percentage spent on each medium.

Television is the chief medium used by national advertisers. The 100 largest advertisers spend an average of 65 percent of their advertising budgets—not including direct mail and sales promotion—on television. Food companies spend about 75 percent of their budgets on television, and companies that make games and toys spend about 90 percent.

A main advantage of television to advertisers is that it brings sight, sound, and action directly to consumers in their homes. Advertisers can explain and demonstrate their products to viewers who are enjoying a TV program and cannot easily avoid the commercials. In addition, network television reaches a vast, nationwide audience at a low cost per viewer. For example, a 30-second commercial on a TV network may cost $1 million. But if 50 million viewers watch the commercial, the advertiser pays only 2 cents for each person who sees the ad.

The majority of TV commercials consist of short *spot announcements,* most of which last 30 seconds. The

commercials are usually run in groups of three to six. Television networks and stations generally limit commercial time to about 10 minutes per hour during *prime time* and 16 minutes per hour during most other broadcast times. Prime time refers to the evening hours, when TV programs draw the largest audience.

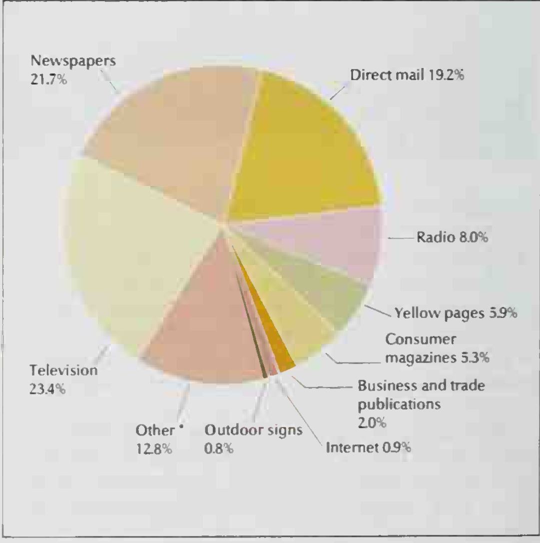
Advertisers can buy *spot time* from local TV stations or *network time* from one of the national TV networks. They can also buy time on cable television. In addition, advertisers can either sponsor an entire TV program or buy *scatter packages*. In scatter packages, the commercials are aired at various times for several weeks. Most advertisers buy scatter packages. But special entertainment programs, sports events, and certain motion pictures are often sponsored by one advertiser. In this way, the advertiser hopes to gain added recognition by being identified with the program.

Newspapers, on the average, devote almost half of their space to advertising. Local businesses and individuals place approximately 85 percent of this advertising. National advertisers sometimes use newspapers to inform consumers of the names and locations of local stores where the advertiser's products are available. National advertisers also use newspapers when they want to concentrate their sales efforts in particular regions of the country.

Newspapers offer advertisers several advantages over other media. Most adults read a daily newspaper, and many of them specifically check the ads for information about products or services. Daily newspapers also offer the advantage of timeliness. An advertiser can prepare and publish an advertisement within a day. Newspaper ads can thus quickly reflect a sudden demand for certain merchandise. For example, a department store can advertise snow shovels in a newspaper the day after the city has its first snowfall of the season.

Newspapers carry two main kinds of advertisements: *display ads* and *classified ads*. Display ads range in size from less than 1 column-inch (1 column wide by 1 inch [2.5 centimeters] deep) to a full page or more, and most include illustrations. Advertisers can appeal to people with special interests by placing their ads on certain pages, such as those devoted to travel, home life, or sports. Classified ads, which are also called *want ads,* appear in a separate section of a newspaper. Most classified ads consist of a few lines of print. The ads list homes, used cars, furniture, and other property that individuals have for sale. Used-car dealers, real estate companies, and firms with job openings also place classified ads. Most newspapers will also accept preprinted ad sections called *free-standing inserts,* which are several pages long.

Direct mail includes leaflets, brochures, catalogs, and other printed advertisements that are delivered by a postal service. Mail-order firms, which sell largely through the mail, are the main users of direct-mail advertising.



The effectiveness of advertising by direct mail depends mainly on the quality of the *mailing list*. Some lists consist of all the addresses in a city and are simply sent to "Occupant." Other mailing lists consist of individual names with addresses. Some firms specialize in preparing lists of people according to their occupation, age, income, interests, or other characteristics. For example, a firm might assemble a list of 20,000 new mothers or 10,000 lawyers. These lists are sold to advertisers. Some advertisers assemble their own mailing lists.

Direct-mail advertising costs more per person reached than do other ways of advertising. However, advertisers who obtain special mailing lists know they are reaching good prospects. In addition, advertisers can choose from many different sizes and forms of adver-

Newspapers and magazines devote large amounts of their space to advertising. The wide variety of publications allows advertisers to target readers of a certain age or location, or with specific areas of interest.

tisements. Some products or services are too complicated to be explained in any other medium.

Radio. Local advertisers place about 70 percent of the advertising on radio stations. The rest is placed by national advertisers, who buy time either from individual stations in various cities and towns or from one of the radio networks.

One advantage of advertising on radio is that people can listen to programs while doing other things. Another advantage is that radio audiences, in general, are more highly selected by the type of programming than are television audiences. For example, stations that feature country music attract different kinds of listeners than do those that play rock. By selecting the station, advertisers can reach the people most likely to buy their products. Radio commercials include direct sales announcements, dramatized stories, and songs. Most commercials last 30 or 60 seconds. In general, radio stations have more commercial time per hour than television stations. Thus, a major drawback of radio is that listeners often hear so many commercials that it is difficult for any one ad to make an impression.

Magazines. Most magazines have a nationwide circulation and so are used chiefly by national advertisers. Magazines have a number of advantages over newspapers as an advertising medium. They are usually read in a leisurely manner and are often kept for weeks or months before being discarded. In many cases, several members of a family read each copy of a magazine. Another advantage of magazines is that they offer better printing and color reproduction than newspapers do. Advertisers can thus show off their products to greater advantage in magazines.

Advertisers can choose from a wide variety of magazines. Some magazines, such as newsmagazines, appeal to a mass audience. Others are designed for specific groups of people, such as teen-agers, homemakers, or amateur photographers. Certain companies advertise in *trade publications,* which are devoted to particular businesses, industries, or professions. For example, farm magazines are used by advertisers who sell agricultural equipment and supplies. Drug firms advertise in medical journals to reach doctors and druggists.

Outdoor signs. Most advertising on outdoor signs is placed by national advertisers. One of the main advantages of outdoor signs is that people pass by the signs repeatedly. In addition, large, colorful signs easily attract attention. However, the ads on outdoor signs must be short and simple because most passers-by see a sign for only a few seconds.

The main kinds of outdoor signs are (1) posters, (2) painted bulletins, and (3) electric spectaculars. Posters, commonly called *billboards,* are the most widely used form of outdoor advertising. They consist of printed sheets of paper that are pasted on large billboards. The billboards are owned by local companies, which rent them by the month to advertisers. Painted bulletins are signs painted on buildings or billboards. Electric spectaculars consist of large illuminated displays. Many feature changing messages and moving pictures. Electric spectaculars are the most expensive kind of outdoor sign.

Other ways of advertising include the use of (1) transit signs, (2) displays, (3) telephone directories, (4) novelties, and (5) the Internet.

Transit signs are small posters placed in or on local trains, subways, buses, and taxicabs. Posters placed inside vehicles can carry a longer message than outside ads because riders have more time to read it.

Displays. Window displays are designed to draw customers into a store. Point-of-purchase displays are arrangements of signs, banners, and other items within a store. These displays highlight certain products and are designed to encourage *impulse buying*—that is, buying without previous thought or planning. Many stores have a promotion department, whose duties include preparing displays. Other stores hire display firms. Many manufacturers supply display materials to retailers that sell their products.

Telephone directories carry ads in a section called

Internet advertising allows companies to reach computer users around the world. Many companies advertise through their own Web sites, through signs displayed on other sites, or in electronic directories.

the *yellow pages.* Some of the ads consist of a few printed lines that give the name, address, and telephone number of local businesses. Others take up more space and are like display ads in newspapers.

Novelties are inexpensive items that many advertisers give away. Such items include calendars, matchbooks, and key rings that carry an advertiser's name and message. People are reminded of the advertiser as long as they use the item.

Internet advertising is the newest and fastest-growing type of advertising. Advertising on the Internet, a worldwide computer network, includes small signs called *banner ads,* as well as listings in electronic directories. Many companies maintain sites on a part of the Internet known as the World Wide Web. A company's Web site may contain information about the company and its products, along with pictures or other artwork.

WORLD BOOK photo by Jeff Guerrant

Novelty items that carry an advertiser's name and message are often given away to potential customers. Such items include calendars, matchbooks, mugs, pens, and T-shirts.

Advertising techniques

Advertising is designed to inform, influence, or persuade people. To be effective, an advertisement must first attract attention and gain a person's interest. It may then provide reasons for buying a product and for believing the advertiser's claims.

Advertisers use a variety of techniques to create effective advertisements. They start with a basic *appeal,* which is the main selling point, or theme, of an advertisement. Advertisers then use certain specific techniques. The most commonly used techniques include (1) attention-getting headlines, (2) slogans, (3) testimonials, (4) product characters, (5) comparison of products, and (6) repetition.

Basic appeals. Advertisers rely on many kinds of appeals to persuade people to buy. In general, appeals can be classified as *informational* or *transformational.* Advertisements that use an informational approach describe the *demonstrable* characteristics of a product. Such ads tell what the product is, how it works, or how it is made. Advertisements that use a transformational appeal stress the ways in which a product will provide personal satisfaction. Such an ad might suggest that the product will satisfy the consumer's need for love, security, or prestige.

Advertisers often use sexual themes that appeal to a person's desire to be attractive. For example, an advertisement for after-shave lotion might suggest that the product will help a man attract women.

To persuade the largest possible number of people, many advertisements combine different types of appeals. Appeals may also be aimed at a large general au-

dience or targeted at a limited group of people, such as business executives or young married couples.

Attention-getting headlines are an important feature of printed advertisements. A successful headline leads a person into reading the rest of the ad. Some headlines attract attention by promising the reader a personal benefit, such as a savings in money or an improvement in physical appearance. Other headlines are cleverly worded to arouse a person's curiosity. Still other headlines carry news, such as an announcement of a new product. Headlines also attract attention by directly addressing a specific group. For example, a headline might read: "For the Young Single Woman." The opening lines in a radio or TV commercial serve the same purpose as headlines in printed ads.

Slogans are short phrases that are used over and over. Good slogans are easy to remember. The majority of slogans are designed to help create a favorable image of a company and its products. Most such slogans do not relate to particular features of a product. Companies also use slogans in advertising inexpensive products, such as chewing gum or soft drinks.

Testimonials are advertisements in which a person endorses a product. The person may be someone who looks like an average user of the product. Advertisers also pay movie and TV stars, popular athletes, and other celebrities to endorse products. A celebrity helps attract attention to an advertisement. Under United States government regulations, endorsers must use the advertised product if they claim they do so.

Product characters are fictional people and cartoon animals or characters that are used in advertisements over a long period. Many advertisers use product characters to deliver sales messages for a whole line of products. The characters become highly familiar to people and so provide lasting identification with a company's products. Product characters are often used in advertising aimed at children because such characters delight many young people.

Comparison of products is used most frequently to sell products that compete heavily with other brands. Advertisers compare their product with similar brands and point out the advantages of using their brand. A competitor's product may be named, or it may be referred to as "Brand X" or "the leading brand."

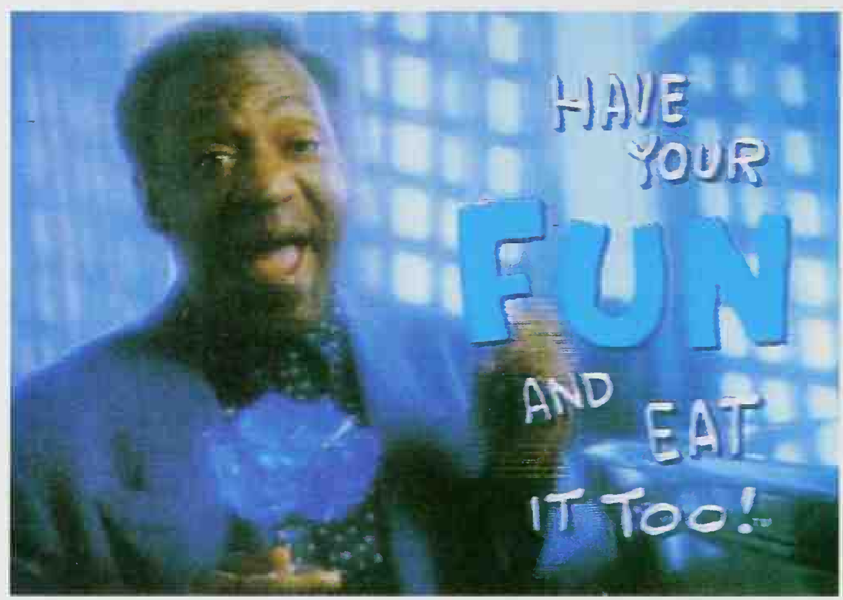
Repetition is one of the most basic techniques advertisers use to get their message across. Advertisers may broadcast their commercials several times a day for weeks on TV or radio. Or they may publish their ads frequently in printed media. Repetition can help build or reinforce a company's reputation. Advertisers also believe that the more often people see or hear an advertisement, the more likely they are to accept the message and want the product.

Creating advertisements

Most business firms hire advertising agencies to create their advertisements and place them in the various media. In most cases, individual advertisements form part of an *advertising campaign.* A campaign is an organized sales effort that may run for several months and that usually involves more than one medium.

In planning an advertising campaign, the agency must first determine the objective of the campaign. The objective may be to prove a product's superiority over competing brands, to change the image of the company, or to achieve some other goal. The agency must also determine the *target market*—that is, the people who are likely users of a product and at whom the advertising will be aimed. Finally, the agency has to estimate how much money and time will be needed to carry out the campaign.

Large advertising agencies generally assign a team of people from the various departments of the agency to handle all the advertising for a specific advertiser, or *client.* The typical agency includes a research department, creative department, media department, and production department. An *account manager,* or *account executive,* has overall responsibility for planning and directing a client's advertising. The following discussion describes in broad terms the way an agency creates advertisements. The main steps in the process include (1) research, (2) media selection, (3) creative work, and (4) production.



Research. Information gathered from consumers provides the basis for many advertising decisions. It helps an agency determine the kinds of people at whom to aim advertisements, the types of appeals to use, and in which media to place the ads. The chief kinds of research include (1) market research, (2) motivation research, and (3) media research.

Market research seeks information about consumers and their buying habits. The information is obtained

© Northwestern Mutual Life Insurance Company (Victor Skrebneski)

An emotional appeal is used in many advertisements to attract attention so that people will learn about the product. This advertisement appeals to parents' love and concern for their children and then gives reasons for buying the product.

Kraft General Foods

Testimonials include advertisements in which a celebrity endorses a product or service. In amusing television commercials, entertainer Bill Cosby, *shown here,* urges viewers to sample Jell-O products.

from a sample of consumers by means of surveys. The information includes the age, sex, income, and occupation of potential consumers. Researchers may also learn how consumers rate various brands of a product, including the advertiser's brand. Such information helps advertisers decide on the best way to present the features of their products.

Motivation research tries to find out why people buy certain products. Motivation researchers gather such information in personal interviews, during which they use techniques developed by psychologists and sociologists. By discovering the motives for people's buying behavior, advertisers hope to find the most effective appeal to use in their advertisements. For example, advertisers may learn that many people buy certain kinds of automobiles chiefly to impress their friends. The motivations of consumers are complex, and the study of motivations is therefore more difficult than most other types of research.

Media research. Various research firms measure the size and makeup of radio and TV audiences at different times of the day. The Audit Bureau of Circulations—an organization of advertisers, advertising agencies, and publishers—measures the circulations of publications. Advertisers use information on audience size and makeup in selecting media in which to place ads.

Media selection. The members of an agency's media department compare the various media in terms of audience size and makeup. They decide which particular magazines, newspapers, and radio and television stations or networks to use to reach the target market. They then prepare a media plan that will give an effective combination of *reach* and *frequency* within the limitations of the budget. Reach is the number of people who will see or hear the advertisement. Frequency is the number of times that they will see or hear it. The media planners may decide to reach a large number of people a few times or to reach fewer people more often.

The recommendations of the media department must be approved by the client. The media planners then buy time and space from the media and schedule the advertisements for specific dates.

Creative work. An agency's creative department develops the central theme of an advertising campaign. The department then designs individual advertisements. The theme, and the ideas for carrying it out, must be approved by the account manager and the client.

For printed advertisements, a copywriter prepares the *copy* (written words) and an artist prepares a *layout* of the advertisement. A layout is a sketch that shows the placement of the copy and illustrations. The illustrations may consist of artwork or photographs or both. The copy, illustrations, and layout may be revised several times. The finished artwork may be prepared by an artist in the agency or by a *free-lance* (independent) artist. Most photographs are taken by professional photographers who are hired by the agency.

For radio commercials, a copywriter prepares the script, which may consist simply of a sales message to be read by a radio announcer. Some scripts are skits that feature dialogue and perhaps sound effects or background music. Original music or songs are written by composers commissioned by the agency.

For television commercials, a copywriter creates the script and an artist designs a *storyboard,* which is a series of drawings of the planned action. The storyboard is combined with the script and includes directions for filming the commercial.

Production. The production of printed advertisements, radio commercials, and TV commercials is arranged by the production department of an advertising agency. The production department deals with *advertising service and supply houses,* which include graphic arts firms and producers of radio and TV commercials. In each case, the client has to approve the final advertisements before they are printed or broadcast.

For printed advertisements, the production department works with graphic arts firms, which set the copy

in type and prepare the film or other material for printing the type and illustrations. This material is then sent to the publications in which the ads will appear. Newspaper advertisements are sometimes produced by the newspaper printers themselves.

For radio commercials, the production department may simply deliver the script to the radio station where it will be read by an announcer. If the script has dialogue, the commercial must be prerecorded, and so the agency hires a radio producer. The producer selects performers to read the commercial and sets up rehearsals. If necessary, a musical director and an orchestra are also hired. The commercial is then recorded on tape in a studio and delivered for broadcasting.

The agency also uses a producer for television commercials. If the commercial is to be filmed or videotaped, the producer may work with a director. These two individuals select performers and arrange rehearsals. After the commercial is shot in the studio or on location, the production department combines it with the sound track and edits it. After the producer has approved the finished commercial, the commercial is sent to the TV stations or network where it will be aired.

Some TV commercials consist of *stop-motion* films or animated cartoons. Stop motion is a method of photographing objects in different positions so that, when the film is run, they appear to move. For example, bottles may seem to dance across a table.

Animated cartoons produced in the traditional way require many individual drawings that must be filmed in sequence. Modern computer-generated animation and special effects are much easier to produce. For example, an electronic device called a *scanner* can convert the colors and shades of illustrations or photos into *digital* (numerical) code, then feed this code to a computer. An animator can then use the computer to manipulate the illustrations.

If the commercial is a live announcement, the producer makes sure the script, product, and furniture or other objects are supplied to the station. The producer also supervises the rehearsals. Today, live announcements are rare.

The advertising industry

The United States has the largest advertising industry in the world. The center of the U.S. advertising industry is New York City, where many of the major agencies have their headquarters. Numerous U.S. agencies have a large international business.

Advertising agencies. The United States has about 6,000 advertising agencies. These agencies range in size from one-person organizations to huge agencies with several thousand employees and with offices in several U.S. and foreign cities. Among the largest United States advertising agencies are Leo Burnett Company Incorpo rated in Chicago and J. Walter Thompson Co. in New York City.

An advertising agency's chief service is to create and place advertising for clients. Some agencies also provide information and advice on selling plans, packaging designs, and other marketing operations.

Advertising agencies receive income in three main ways: (1) from commissions paid by the media, (2) from service charges paid by clients for materials and work purchased from graphic arts firms and other companies, and (3) from fees paid by clients. The standard commission is 15 percent of the cost of the space or time that an agency buys for a client. The agency charges the client the total cost of the space or time and deducts 15 percent before paying the media.

Advertising departments. Most large business companies have an advertising department. In some companies, the department prepares all the company's advertising and so functions as an *in-house agency.* Among those firms that employ an advertising agency, the company's advertising department works closely with the agency. The department might also prepare such materials as point-of-purchase displays and direct-mail brochures, which are not usually considered part of an agency's duties.

Some companies that manufacture a large number of products have *brand managers.* A brand manager supervises the advertising and promotion of one or a few products.

Newspapers, magazines, and radio and television stations and networks also have advertising departments. These departments collect and publish information designed to persuade advertisers to use their particular media vehicle. They supply advertisers and advertising agencies with reports on the vehicle's circulation, listening audience, or viewing audience. They may also provide production assistance.

Advertising associations work to promote the industry and to raise the standards of advertising. The leading national advertising organizations include the American Association of Advertising Agencies, the American Advertising Federation, and the Association of National Advertisers.

Two other important advertising organizations are the Advertising Council and the National Advertising Review Board. The Advertising Council prepares public service ads, such as those that promote highway safety and energy conservation. The National Advertising Review Board fosters self-regulation of the advertising industry. It evaluates complaints about *deceptive* (false or misleading) advertisements. If the council judges an advertisement to be deceptive, it asks the advertiser to discontinue the ad.

Regulation of advertising. Both the U.S. government and the state governments have laws designed to protect consumers from deceptive advertising. They also have laws that prohibit certain kinds of advertising. For example, a federal law bans cigarette advertising on radio and television. But the Supreme Court of the United States has ruled that advertising and the advertising industry have some protection under the First Amendment to the U.S. Constitution. Thus, regulations concerning advertising must be no more restrictive than necessary to accomplish the goals of state and federal governments.

Federal laws against deceptive advertising are enforced chiefly by the Federal Trade Commission (FTC). The FTC monitors all advertising and may ask advertisers for proof of their claims. If the FTC decides that an advertisement is false or misleading, it may order an advertiser to withdraw the ad. The FTC may further require an advertiser to run "corrective" advertising to inform the public that former advertisements were deceptive.

However, the FTC rarely requires this. Advertisers may be fined for violating an FTC order. Some advertisers are also subject to regulation by the Federal Communications Commission (FCC), the Food and Drug Administration (FDA), the Securities and Exchange Commission (SEC), and certain other federal agencies.

Advertising in other countries. Many of the largest advertisers in the United States also spend significant amounts of money to advertise in other countries. These companies may use local agencies or branch offices of U.S.-based agencies to create ad campaigns. Many large U.S. agencies have acquired foreign-based local agencies or developed a network of international offices to handle the advertising of multinational corporations. WPP Group, based in London, and Interpublic Group and Omnicom Group, both based in New York City, are among the largest advertising agencies in the world. Another large agency is Dentsu, in Tokyo.

In Western Europe, government had regulated broadcasting tightly until the 1980's. The state owned the broadcast industry, each country had only one or two television channels, and the amount of advertising time was severely restricted. In the 1980's, more channels were added by the state and private companies, and advertising restrictions were loosened. In addition, satellites began to beam TV signals to rooftop antennas on individual homes. Most such signals reach consumers in more than one country. Because of increased access to consumers, the trend among major European advertisers has been to develop a single ad campaign for several countries.

AP/Wide World

International ad campaigns can spread an advertiser's message to people throughout the world. This billboard for a U.S.-based computer company appeared in Yangon, Myanmar.

Regulations on advertising differ in other parts of the world. In Australia, for example, most ads must be produced locally. China charges higher ad rates for foreign advertisers than for local companies or joint ventures.

Agencies throughout the world support the International Advertising Association, which has headquarters in New York City. This organization works for truth in advertising, the protection of commercial speech, and improvements in the quality of media research.

Effects of advertising

Advertising greatly influences many aspects of life in the United States. This section deals with some of its economic, social, and political effects.

Economic effects. Advertising plays a major role in the distribution of goods from manufacturers to consumers. It provides an effective way for sellers to inform buyers about products. Advertising thus helps manufacturers sell their products and benefits consumers by providing them with shopping information.

Advertising also helps the economy grow by stimulating demand for new products. Manufacturers spend much money to develop new products. Through advertising, they can speed up the process of creating a market for a product and so recover their costs more quickly. Fewer new products would be developed if manufacturers could not use advertising to help sell the products.

Some economists believe that a large amount of the money spent on advertising is wasted. They argue that much advertising simply leads consumers to switch from one brand of a product to another brand. Brand-switching may increase the profits of a particular firm but has no positive effect on the overall economy.

Advertisers include the expense of advertising in the sales price of a product. In some cases, advertising raises the price of a product. In other cases, advertising helps lower prices by creating the *mass demand* that supports mass production. Successful advertising makes many people want a product. By mass producing a product and developing a large volume of sales, the manufacturer can charge less per unit.

Social effects. Perhaps the most important social contribution of advertising is that it supports the mass communication media. Advertising pays all the costs of commercial television and radio. It provides viewers with free entertainment and news programs, though viewers are often irritated by commercial interruptions. Advertising also pays three-fourths of the costs of newspapers and magazines. Without advertising, readers would have to pay a higher price for newspapers and magazines, and many of the publications would go out of business.

Because the mass media depend on advertising to stay in business, many people question whether advertisers control the media. Generally, media do not allow advertisers to influence their programming or editorial content. However, many broadcasters and publishers do not hesitate to run favorable information about their advertisers, and they sometimes refuse to run unfavorable information. Critics of commercial television maintain that dependence on advertising lowers the quality of TV programming. In order to sell advertising time at high

Political advertising has played an important role in election campaigns since the mid-1900's. President Dwight D. Eisenhower, shown here with his wife, Mamie, used television to reach out to voters during the 1950's.

prices, TV stations try to attract the largest possible audience. Critics argue that the stations therefore broadcast too many general entertainment programs and not enough informational and cultural programs.

Many critics also charge that advertising persuades people to buy products they do not need or want through the use of psychological techniques. Advertisers reply that they do not have the means to make people buy unwanted products. They argue that adults freely choose what to buy or what not to buy. Most experts agree, however, that advertising is particularly persuasive to young children, who do not have the ability or experience to judge advertising critically. For this reason, the Federal Trade Commission has strict regulations governing advertising aimed at children.

Political effects. Little attention was paid to political advertising until 1952, when Dwight D. Eisenhower successfully ran for the U.S. presidency. Advertising executives, rather than politicians, directed Eisenhower's presidential campaign. Much of Eisenhower's campaign consisted of a flood of spot announcements on television stations.

Since 1952, advertising executives have played an increasingly important role in political campaigns. In addition, TV spot announcements have become a major feature of campaigns for public offices at the national and state levels. The chief criticism of political advertising concerns the use of such spot announcements, which may concentrate on creating an image of a candidate and tend to oversimplify the issues. Critics object to candidates being "sold" through advertising methods like those used to sell products. Another complaint is that candidates with the most money to spend on advertising have an unfair advantage over their opponents. Because of this complaint, Congress passed a law in 1974 that limits the amount of money candidates may spend in presidential campaigns.

History

Most historians believe that outdoor signs above shop doors were the first form of advertising. As early as 3000 B.C., the Babylonians, who lived in what is now Iraq, used such signs to advertise their stores. The ancient Greeks and Romans also hung signs outside their shops. Few people could read, and so merchants used symbols carved in stone, clay, or wood for the signs. For example, a bush indicated a wine shop, and a boot advertised a shoemaker's shop.

In ancient Egypt, merchants hired *criers* to walk through the streets and announce the arrivals of ships and their cargo. By the A.D. 900's, town criers, who called out the news, were common in European countries. They also were hired by merchants to direct customers to shops and to tell them about goods and prices in the marketplace.

The impact of printing. About 1440, Johannes Gutenberg of Germany invented movable type in Europe. His invention led to the first forms of mass advertising—printed posters, handbills, and newspaper ads. William Caxton, who introduced printing into England, produced the first printed advertisement in English in 1472. It was a poster announcing the sale of a book and was tacked on church doors.

The first newspaper regularly printed in England, a weekly newssheet, appeared in 1622. In the years that followed, more English newspapers were started, and advertising soon became a standard feature of newspapers.

The first newspaper advertisement in the American Colonies appeared in *The Boston News-Letter* in 1704. Many of the early magazines in the United States either refused to print advertisements or carried only certain kinds of ads. But in the mid-1800's, more and more magazines began to accept advertising, and magazine advertising grew quickly. Some magazines were started chiefly to earn advertising money.

Many early ads in both the United States and England paid little heed to the truth. Advertisers made wildly exaggerated claims. Ads for nonprescription drugs, for example, boasted cures for all kinds of ailments.

The development of advertising agencies. The first advertising agencies acted as *brokers*—that is, they bought space at a discount from newspapers and resold it to advertisers. The ads were prepared by the advertisers themselves or by hired writers.

Historical Pictures Service

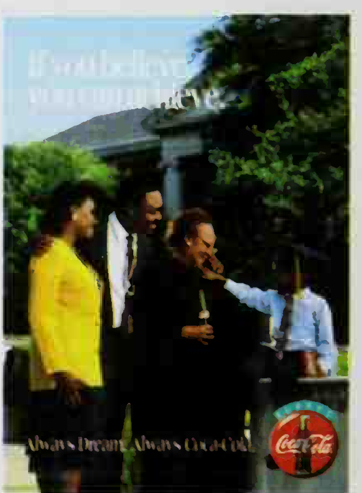
Exaggerated claims were made in many ads in the 1800's for medicines and such "medical aids" as electric belts, *shown here.*

Volney B. Palmer started the first U.S. advertising agency in Philadelphia in 1841. Palmer worked as an agent for newspaper publishers. He received 25 percent commission on the space that he sold to advertisers.

In 1875, N. W. Ayer & Son, another Philadelphia advertising agency, began to emphasize agency services to advertisers. In time, the firm hired writers and artists and carried out complete advertising campaigns for clients. N. W. Ayer & Son thus became the first "modern" advertising agency. By 1900, most agencies in the United States were writing copy for advertisers. By the 1920's, they had assumed responsibility for complete advertising campaigns.

The rise of radio and television provided advertisers with new, powerful media. Commercial radio stations began operating in the United States in the 1920's. Radio soon became a major medium for national advertisers. It enabled them to reach the large, captive audiences that tuned in to popular programs. Many of the radio shows were produced by advertising agencies. The popularity of radio soared for about 20 years, until television began to boom after World War II (1939-1945). Radio then lost much of the business of national advertisers, though it continued to be an important medium for local advertisers. The rise of coast-to-coast TV broadcasts in the 1950's provided national advertisers with access to mass audiences far larger than those reached by radio. By 1955, advertisers were spending over $1 billion a year on television.

Recent developments. Advertising expenditures in the United States have increased tremendously since World War II. In 1950, about $5.7 billion was spent on advertising. Advertising expenditures are now more than $200 billion a year.



The growth of advertising since the 1950's has been accompanied by criticism of advertising practices. Much of the criticism has focused on the use of psychological techniques in advertising. Advertising has also been criticized for its stereotypical portrayal of women, elderly people, and racial minorities. As a consequence, many advertisers have broadened the variety of roles played by members of these groups in ads. In addition, some advertisers have used people with physical disabilities in commercials for products and services not related to the disabilities.

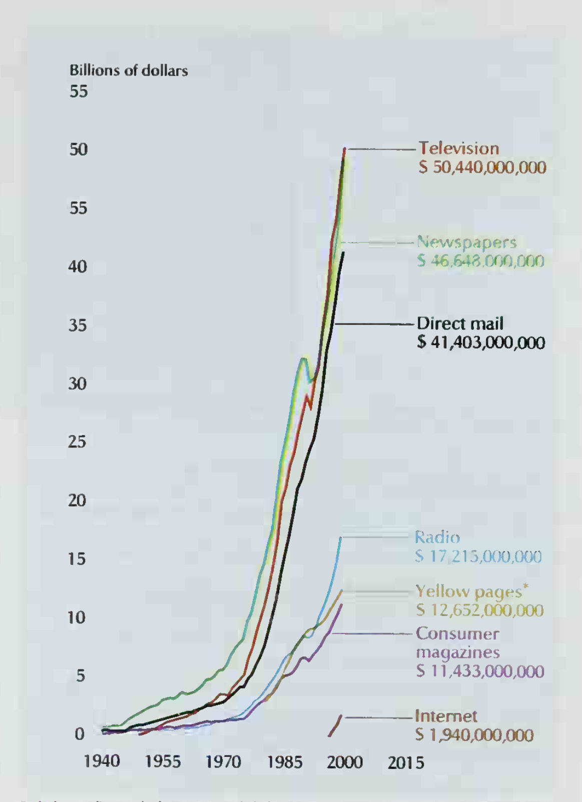
Coca-Cola Company

Advertising over many years has helped establish the widespread popularity of Coca-Cola. Distinctive slogans and an emphasis on youth, enjoyment, and success have long characterized Coke ads. The company regularly updates its ads to appeal to more consumers.

Total growth of U.S. advertising



This graph shows how U.S. advertising expenditures have risen since 1950. The rise has been especially marked since 1970.

Growth of U.S. advertising by medium

This graph indicates how advertising expenditures in the United States have been distributed since 1940 among the chief media.

Excludes media on which comparatively little money is spent, such as outdoor signs and store displays. *Information for yellow pages not counted separately prior to 1980.
Source: Universal McCann, Inc. Figures are for 1999.

Since the 1980's, many new advertising media have appeared. For example, advertisements are now seen in motion-picture theaters and on videotapes prior to the featured movie. They appear in high school classroom news programming. Supermarket shoppers may be exposed to in-store radio and grocery carts with miniature billboards or video screens advertising products.

Advertising on the Internet began after the creation of the World Wide Web in the early 1990's. Businesses spend only a small percentage of their advertising budgets on the Internet, but this medium is growing rapidly.

Advertisers also began to spend more money on promotional campaigns. Promotions involving coupons, rebates, premiums, or sweepstakes awards may provide a short-term boost in sales. But some industry experts believe the increase in sales comes at the expense of the long-term image of the brand or product.

Careers

The field of advertising offers a wide variety of job opportunities for people with creative, analytic, business, or technical skills. The industry needs writers, artists, researchers, media buyers, salespeople, production managers, and account executives. Jobs can be found with advertisers, advertising agencies, the advertising media, or advertising service and supply houses.

The majority of jobs in advertising require a college education or special training. Approximately 30 colleges and universities in the United States offer major programs in the field of advertising. People with education in the liberal arts, journalism, behavioral sciences, business, or commercial art may also find employment in the advertising industry.

Information about careers in advertising may be obtained from the American Advertising Federation in Washington, D.C., and from the American Association of Advertising Agencies in New York City.

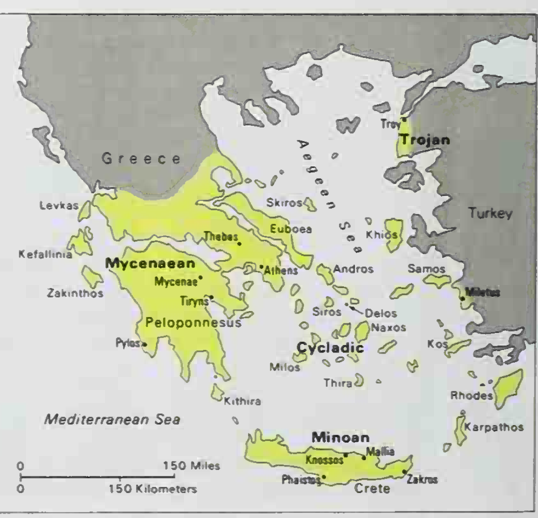
Aegean civilization, *ih JEE uhn,* consisted of four cultures that flourished on the islands and shores of the Aegean Sea between 3000 and 1200 B.C. These cultures are called the *Cycladic, Minoan, Mycenaean,* and *Trojan* cultures. The Cycladic culture developed on a group of islands called the Cyclades. The Minoan culture arose on the island of Crete, and the Mycenaean culture flourished on the mainland of Greece. The Trojan culture centered upon the ancient city of Troy in what is now northwestern Turkey.

The Aegean civilization arose after the people of the area discovered how to make bronze. During this period, called the Aegean Bronze Age, the people became highly skilled in architecture, painting, and various crafts. They built richly decorated palaces and used systems of writing. The Aegean Bronze Age ranks as one of the greatest artistic and cultural ages in history. It lasted from about 3000 to about 1100 B.C.



The Aegean civilization collapsed in the 1100's B.C. The craftwork skills, the systems of writing, and the building knowledge were lost, and most trade ended. The region made little progress during the next 300 years.

The Aegean people left no written history. However, their descendants told stories about gods, great kings and heroes, and bloody wars. Some of these stories may have been based on actual people and events. The tales formed the basis for the epics the *Iliad* and the *Odyssey,* attributed to the Greek poet Homer. The Aegean people also kept some records written on clay tablets. These records were written in characters that were not deciphered until A.D. 1953.

Archaeologists have uncovered most of the information known about the Aegean civilization. In the 1870's, the German archaeologist Heinrich Schliemann began research on the civilization. He believed that many stories in classical Greek literature were based on real events, and he searched for the sites of legendary cities. In 1870, using legends as a guide, Schliemann conducted the first major excavation on the site of Troy. In 1876, he launched the study of the Mycenaean culture. Schliemann discovered royal graves in Mycenae on the Greek mainland.

In the 1880's, James T. Bent, a British scholar, explored the Cycladic culture. In 1900, Sir Arthur Evans, another British scholar, began excavating the Palace of Minos in Knossos on the island of Crete. His research provided most of the present-day knowledge of the Minoan culture.

The Cycladic culture flourished on a number of Aegean islands, including Kos, Milos, Siros, and Thira. Many Cycladic people made their living by fishing. Others worked as sailors and traders. Still others were

WORLD BOOK map

Aegean civilization flourished on the islands and shores of the Aegean Sea between 3000 and 1200 B.C. Four cultures—the Cycladic, Minoan, Mycenaean, and Trojan—developed there.

Ronald Sheridan

The Aegean people were highly skilled architects, artists, and craftworkers. The Minoans on the island of Crete produced such works as the scene shown here. The painting, which dates from between 1600 and 1400 B.C., shows people offering gifts to a god.

farmers, many of whom grew grapes for use in producing wine. Cycladic craftworkers made distinctively designed pottery and stone figurines. After 1900 B.C., the Cycladic culture declined and adopted many features of the Minoan and Mycenaean cultures.

The Minoan culture, which arose on Crete, was named for Minos, the legendary king of the island. According to tradition, Minos ruled the Aegean Sea and kept the *Minotaur,* a monster that was half man and half bull. See Minos; Minotaur.

The Minoans were skilled artists and architects and active traders. They built the Palace of Minos in Knossos, as well as palaces in Zakros, Mallia, and Phaistos. The Minoans established trading posts throughout the Aegean region and in Egypt. Other people of the Aegean area copied Minoan designs in pottery and other craftwork. The Minoans developed a decimal system and used a writing system in which complex symbols represented syllables of words. The Mycenaeans on the mainland of Greece later adapted the Minoan writing system to their language.

After about 1450 B.C., fire destroyed nearly all the towns and palaces on Crete. But the palace in Knossos survived, and Mycenaeans gained control of it. The palace was burned by other people from Greece in the early 1300's B.C. The Minoan culture began to decline after the palace was burned. The culture disappeared in the mid-1100's B.C.

The Mycenaean culture, also called the *Helladic culture,* centered on Mycenae, a powerful city on the mainland of Greece. By about 2000 B.C., a group of people had moved to the Peloponnesus, the southern peninsula of Greece, and had established Mycenae. Archaeologists do not know where these people came from. The people introduced new styles of pottery to the area and built houses that had a large central room. Scholars believe the Mycenaeans may have spoken a dialect that later developed into the Greek language.

By the 1500's B.C., the Mycenaeans had grown rich and powerful, and they greatly influenced Greek culture. For this reason, archaeologists call the late Bronze Age in Greece the *Mycenaean period.* The Mycenaeans used Minoan architecture as a model for their palaces. During the 1300's B.C., they built palaces in Mycenae and in such places as Athens, Thebes, Pylos, and Tiryns. The palace in Mycenae was surrounded by massive walls with a huge gateway called the *Lion Gate.*

About 1200 B.C., the Mycenaean civilization had collapsed, and its main centers had been destroyed. Scholars do not know whether the civilization fell because of internal disorder or under attack from invaders. According to one traditional account, the Mycenaeans were invaded by the Dorians, a people from northwestern Greece. But many experts now believe the Dorians did not arrive until after the fall of the Mycenaeans.

The Trojan culture, also called the *Troadic culture,* developed in and around Troy. Archaeologists have uncovered the remains of nine cities on the site of Troy. Each successive city was built on the ruins of the one before it. Archaeologists believe the seventh city was the legendary Troy described in the *Iliad* and the *Odyssey.* This city was built during the early 1200's B.C. It was set afire and destroyed in the mid-1200's B.C., possibly by invaders from the mainland of Greece.

Aegean Sea, *ee JEE uhn,* is a gulf or arm of the Mediterranean Sea. It lies between Greece on the west and north, Turkey on the east, and the island of Crete to the south. Its southernmost part is called the Sea of Crete. The Aegean covers about 69,000 square miles (179,000 square kilometers). It is about 400 miles (640 kilometers) long and more than 200 miles (320 kilometers) wide at its widest point. The Dardanelles, a strait on the northeast shore, links the Aegean to the Sea of Marmara.

Many islands, together known as the Grecian Archipelago, lie throughout the Aegean Sea. They form four main groups—the Cyclades, the Dodecanese, the Sporades, and a widely scattered group in the northern Aegean that includes Limnos and Thasos. The beautiful islands of the Aegean achieved fame in Greek history and legend. Some are ancient volcanoes and are made of lava. Others are made of pure white marble. The important historic islands include Delos, Euboea, Samos, Lesbos, Lemnos, Patmos, and Rhodes. All the islands of the Grecian Archipelago have an area of about 2,500 square miles (6,470 square kilometers). John J. Baxevanis

WORLD BOOK map

Aegis, *EE jihs,* was the name of the shield or breastplate made for Jupiter by Vulcan. Jupiter created thunder with it. Minerva (Athena), Jupiter's daughter, carried it as a sign of authority when she went on missions for her father. In its center was the head of Medusa, which is said to have had the power of turning men to stone.

See also **Medusa; Minerva.** Mary R. Lefkowitz

Aeneas, *ih NEE uhs,* was a Trojan hero in Greek and Roman mythology. The Romans believed he was an ancestor of Romulus and Remus, the mythical founders of Rome. The Roman poet Virgil celebrated the adventures of Aeneas in the *Aeneid,* Rome's national epic.

Aeneas was the son of the Trojan prince Anchises and the Greek goddess Aphrodite (called Venus by the Romans). When Troy fell, Aeneas fled with his father and his son Ascanius from the burning city (see **Trojan War**). On nearby Mount Ida, Aeneas gathered the few other Trojan survivors and sailed away to found a new home. They stopped at various places and had many adventures. In the city of Carthage in Africa, Aeneas met Queen Dido. She fell in love with him and committed suicide when a sense of duty to his destined role as a founder of a new home for the Trojans compelled him to leave her.

Aeneas finally arrived in Italy. He visited the lower world, where he learned about Rome's future glory. Aeneas then traveled to the Italian region of Latium, where he became friends with King Latinus. The king offered his daughter Lavinia in marriage. Aeneas married Lavinia and founded the city of Lavinium.

Aeneas later disappeared from this world during a battle with a neighboring people called the Etruscans. According to some versions of the myth, he was taken to heaven and became the god Jupiter Indiges.

Daniel P. Harmon

See also **Aeneid; Dido; Virgil.**

Aeneid, *ih NEE ihd,* the national epic of ancient Rome, is one of the world's greatest poems of heroic adventure. It was written by the Roman poet Virgil between 30 and 19 B.C. This period was one of national pride for the Romans. The emperor Augustus had just united the people of the Italian peninsula to defeat Rome's enemies in the eastern provinces. Virgil chose the myth of the Trojan hero Aeneas to express ancient Rome's moral and religious values and to honor Augustus, who was believed to be Aeneas' descendant.

The *Aeneid* contains 12 books. The first six books imitate the Greek epic the *Odyssey.* They describe Aeneas' adventures at sea following the capture of Troy by the Greeks during the Trojan War.

As the *Aeneid* begins, a storm shipwrecks Aeneas and his Trojan followers near Carthage in North Africa. There, Aeneas falls in love with the queen, Dido. But the gods order him to leave for Italy. In despair, Dido commits suicide. After Aeneas finally reaches Italy, he goes down to the underworld and learns about his future descendants, the Romans.

Virgil bases the last six books of the *Aeneid* on the Greek epic the *Iliad.* They begin as Aeneas arrives near the future site of Rome. There, the local king, Latinus, offers him land for his people and marriage to his daughter, Lavinia. Turnus, Lavinia's jealous suitor, attacks the Trojans and kills the young soldier Pallas, whom Aeneas has promised to protect. Aeneas later fights Turnus and kills him in punishment for the death of Pallas.

Aeneas' obedience to the gods costs him his personal happiness and the lives of those he loves. Yet he retains his sense of duty and commitment to creating a new nation in an unknown land. Elaine Fantham

Aeolian harp, *ee OH lee uhn,* is an unusual ancient musical instrument. It consists of a wooden box with from 8 to 15 strings of various thickness stretched along the top. The strings are raised slightly by low bridges near each end of the box. The instrument produces soft, exotic sounds when the wind blows on the strings, causing them to vibrate. The Aeolian harp is named for Aeolus, the ancient Greek god of the winds. Abram Loft

Aeolians, *ee OH lee uhnz,* were a group of ancient Greeks. They lived in a large part of east-central Greece before 1150 B.C. Toward the end of the 1100's, other

Greeks called Dorians invaded Aeolian territory, and many Aeolians moved to the western coast of Asia Minor (present-day Turkey) and the nearby islands of Lesbos and Tenedos. The coastal district was known as *Aeolis.* The Aeolians organized themselves in a loose confederacy. The island of Lesbos became a busy trading center and the home of a famous school of poetry. Its most famous poets included Alcaeus and Sappho.

Norman A. Doenges

See also Achaeans; Dorians; Greece, Ancient (History); Ionians; Sappho.

Aeolus, *EE uh luhs,* was the keeper of the winds in Greek mythology. Aeolus lived on a floating island, which scholars believe was one of the Aeolian Islands near Sicily. These islands were named for him. Aeolus kept the winds confined in a cave on the island and released them whenever he wished.

Aeolus plays an important part in two great epic poems, the *Odyssey* and the *Aeneid.* In the *Odyssey,* Aeolus gives the Greek hero Odysseus (Ulysses in Latin) a leather bag containing the winds that could prevent Odysseus from sailing home. Odysseus's sailors open the bag because they mistakenly believe that it contains treasure. The winds escape from the open bag and blow Odysseus's ship off its course. At the beginning of the *Aeneid,* the goddess Juno, an enemy of the Trojan hero Aeneas, persuades Aeolus to release winds that cause a storm. The storm then scatters Aeneas's fleet.

Aerobatics. See Airplane (Special-purpose planes; picture: Aerobatic planes).

Aerobics, *air OH bihks,* is a system of exercises designed to promote the supply and use of oxygen in the body. These exercises include bicycling, dancing, jogging, rowing, skating, swimming, and fast walking. Many people participate in aerobics programs to increase their endurance and energy and to achieve and maintain their proper weight. Regular aerobic exercise may also help lessen the risk of heart disease.

A regular, vigorous program of aerobic exercises helps the body process large amounts of oxygen efficiently. The presence of oxygen in the muscle cells is necessary for the formation of a compound called *adenosine triphosphate* (ATP). The breakdown of ATP produces the energy for all muscular activity. During vigorous activity, more oxygen is inhaled and passes from the lungs into the blood. More oxygen-rich blood is delivered to the muscles, creating more ATP. This increased amount of ATP produces more energy for the body. If the circulatory system cannot supply enough oxygen to the muscles or if the muscles cannot use oxygen efficiently, the body produces a smaller amount of ATP. This results in early fatigue.

For maximum effectiveness, individuals should perform aerobic exercises continuously for 15 minutes to an hour 3 to 5 times a week. Men and women over the age of 35 should get a medical examination before beginning an aerobics program. Herb Weber

Aerodynamics, *AIR oh dy NAM ihks,* is the study of forces that act on an object as it moves through air or some other fluid. Aerodynamic forces act on airplanes and all other objects that fly through the air. These forces also act on automobiles and other objects that move partly through the air and partly along a solid surface. In addition, aerodynamic forces act on ships, which move partly through the air and partly through water. Such forces even act on buildings due to the wind that blows around them. Scientists, engineers, and architects study aerodynamics to learn to design vehicles and structures.

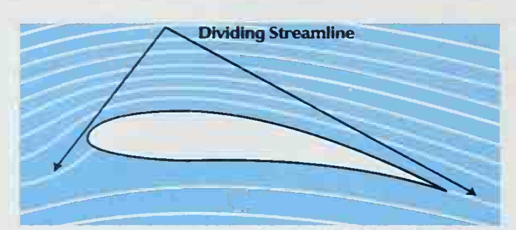
Principles of aerodynamics

There are two basic aerodynamic forces—*lift* and *drag.* Both result from a transfer of force from a fluid to the surface of a solid object. The force from the fluid creates a *pressure* and a *shear stress* on the surface.

Pressure is force per unit area, with the force applied perpendicular to the surface. Pressure can be measured in *pounds per square inch* in the system of units customarily used in the United States. The pounds are a measure of the force, and the square inch is the unit of surface area. In the metric system, a common unit of pressure is the *kilopascal.* One kilopascal equals a force of 0.1 newton on an area of 1 square centimeter. One pound per square inch equals about 6.9 kilopascals.

Shear stress is also force per unit area, but this force is applied along the surface. Shear stress occurs in a fluid due to the fluid's *viscosity,* its internal friction that resists motion. Friction occurs in a fluid whenever one layer of the fluid slides over another layer. Because of friction, the layers resist sliding.

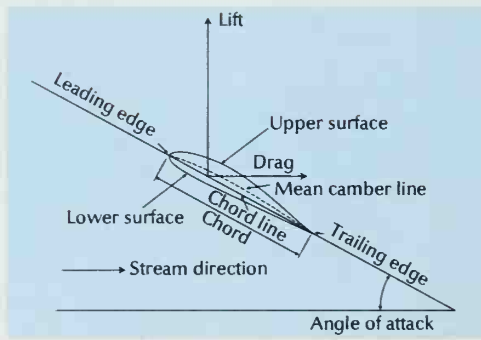
The *total aerodynamic force* transferred from the fluid to the surface is a result of the pressure and the shear stress acting over the entire surface. Lift and drag are *components* (parts) of the total aerodynamic force. Lift is the component that is perpendicular to the direction of motion of the object. In the case of an airplane that is flying horizontally, the lift is applied in the upward direction. Drag is the component that pushes in the direction opposite that of the object's motion. Thus, drag opposes the motion of the object.



Lift keeps an airplane in the air by balancing the weight of the plane. This aerodynamic force is created along a wing by the motion of the wing through the air.

Lift can be analyzed in terms of the motion of an *airfoil* (cross section of a wing) through the air. The motion creates lift by producing a difference in air pressure. The air pressure on the lower surface of the airfoil becomes greater than the air pressure on the upper surface.

The pressure difference is a result of a difference in the speed of the air flowing along the two surfaces. According to a principle discovered by Daniel Bernoulli, a Swiss mathematician, the pressure of a fluid increases as the speed of the fluid decreases. The air pressure on the lower surface of the airfoil is greater because the air flows more slowly along that surface.



Lift can occur when the airflows along the top and bottom surfaces are *unsymmetrical* (unbalanced). Unsymmetrical flow is a result of one or both of the following factors: (1) the *camber* (curved shape) of the airfoil and (2) the *angle of attack* (the angle at which the airflow meets the airfoil). A typical airfoil has a rounded

How lift occurs

WORLD BOOK diagram by Jonathan Simpson

Lift can occur when the airflows along the top and bottom surfaces of an airplane wing are *unsymmetrical* (unbalanced). The air approaching the wing's rounded edge splits smoothly along a line called a *dividing streamline* and merges smoothly at the sharp edge.

WORLD BOOK diagram by Jonathan Simpson

Factors that create lift in an airplane include (1) the *angle of attack* that each wing makes with the airstream and (2) the shape of the *mean camber line* that represents the average curvature of the wing's upper and lower surfaces. At the leading edge of the wing, the mean camber line curves upward from the straight *chord line* connecting the leading and trailing edges.

leading (front) edge and a sharp *trailing* (rear) edge. As the air approaches the leading edge, it splits to go around the airfoil. The air that travels along the top accelerates as it goes around the highly curved leading edge. As a result, the speed of the air on the upper surface is greater.

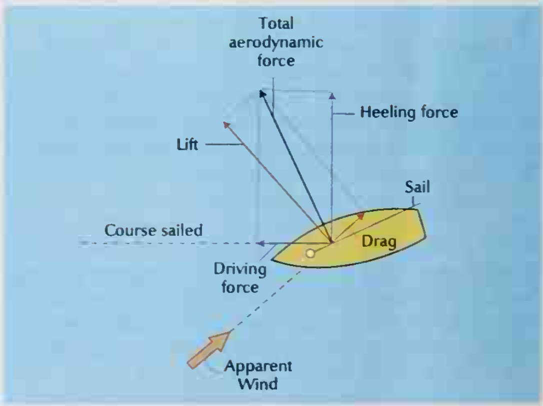
In addition, the airflows along the top and bottom of the airfoil merge smoothly as they leave the trailing edge. This condition is known as the *Kutta condition*—named for its discoverer, Martin W. Kutta, a German mathematician.

Another explanation for lift is related to an airfoil's ability to *deflect* (turn) air downward. An airfoil deflects air by guiding the air along its cambered surface and by meeting the air at an angle. Deflection produces lift according to a law of motion explained in 1687 by the English scientist and mathematician Isaac Newton. This law states that, for every action, there is an equal and opposite reaction. Thus, as an airfoil deflects air downward, the reaction to the deflection produces an upward force by the air on the airfoil.

The amount of lift created by the airflow along a wing depends mainly on the wing's angle of attack, speed, and camber. The area of the wing and the density of the air also affect the amount of lift.

Angle of attack is the angle that a wing makes with the air flowing past it. A pilot can change this angle by changing the plane's position in space. Increasing the angle of attack increases the lift—but only up to a point. If the angle of attack becomes too large, the airflow will separate from the upper surface of the wing. As a result, lift will decrease sharply, producing a condition called *stall.* An airplane at the point of stalling may crash unless the angle of attack is quickly reduced. Airplanes fly at angles of about 3 to 15 degrees. An airplane will stall if the angle becomes larger than 15 or 20 degrees.

Speed. A wing's speed through the air helps determine how much lift will occur. The faster the airplane is flying, the greater will be the lift.



Wing area. An increase in wing area creates extra lift by increasing the total forces due to air pressure and shear stress. If the air pressure and the shear stress are held constant, the amount of force depends only on the area: The greater the area, the greater the force.

Air density. Air that is relatively dense creates more lift than does relatively thin air. This happens because, according to Bernoulli's principle, pressure increases with density.

Creating extra lift. During take-offs and landings, pilots want to fly as slowly as possible. Special parts called *high-lift devices* enable a plane to fly at minimum speeds. These devices are extensions that fit smoothly against the wing while the airplane is cruising. The pilot can lower them when they are needed. The extension at the leading edge of the wing is called a *slat.* The extension at the trailing edge is a *flap.* When lowered, these extensions increase the wing camber and area, furnishing extra lift.

Drag is a force that resists the forward motion of a solid object in a fluid. The object's shape affects the amount of drag. Objects shaped to produce little drag are called *streamlined* or *aerodynamically clean.*

Two types of drag—*friction drag* and *form drag*—act on all moving objects. A third type, *induced drag,* affects

WORLD BOOK diagram by Jonathan Simpson

A boat sails into the wind. When the wind blows past the sail, it creates a total aerodynamic force that can be represented by a *driving force,* which propels the boat, and a *heeling force.* This diagram also shows lift and drag forces for comparison with the corresponding forces on an airplane wing.

only objects with lift. Still another kind of drag, *wave drag,* results when an object moves faster than the speed of sound. Wave drag also occurs when a ship generates waves on the surface of the water. This section discusses friction drag, form drag, and induced drag. For a discussion of wave drag, see the section *Shock waves* later in this article.

Friction drag is a component of the drag due to shear stress. Friction has its strongest effect in the *boundary layer,* a thin layer of fluid next to the surface.

The amount of friction drag depends upon whether the fluid flow is *laminar* or *turbulent.* In laminar flow, the fluid molecules move in orderly paths essentially along the direction of the surface. Turbulent flow occurs at higher speeds. In turbulent flow, the fluid's speed and direction of flow vary randomly from an average value. This variation increases the shear stress. As a result, friction drag is much higher when flow is turbulent than it is when flow is laminar.

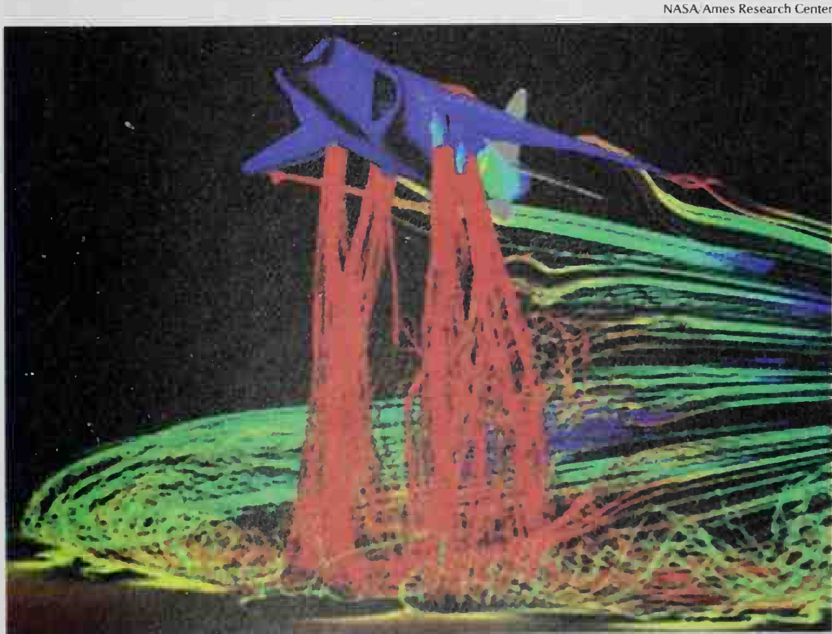
Airflow is usually laminar near a wing's leading edge, and it becomes turbulent farther along the surface. Airplane designers try to delay the change from laminar flow to turbulent flow. One way to do this is to make the surface as smooth as possible.

Form drag is a component of the drag due to pressure. The amount of form drag on an object depends on the object's form, or shape. If the object is not streamlined, the drag force is mostly form drag. If the object is streamlined, the drag force is mostly friction drag.

In form drag, the flowing fluid separates from the object. The pressure next to the rear surface of the object therefore decreases. This decrease makes the pressure on the front surface larger than that on the rear surface. The net result is a force that pushes against the front of the object. This force is the form drag. Designers can reduce form drag by streamlining the object.

Induced drag is a result of a phenomenon that is also responsible for lift. Airflow will lift an airplane wing if the air pressure on the wing's lower surface is greater than that on the upper surface. But this pressure difference also makes air flow at the tip of the wing. The air at the tip moves from the lower surface to the upper surface. This flow creates *vortices,* swirling streams of air that flow away from the tip and continue behind the wing.

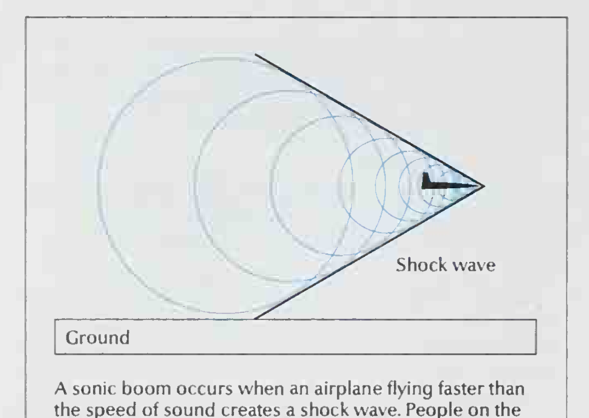
The creation of wing-tip vortices uses energy that could otherwise be spent to provide lift and propel the aircraft. In addition, the vortices threaten the safety of airplanes flying close behind. Aircraft designers lessen induced drag by giving airplanes long, narrow wings.



Lift and drag in a sailboat. The principles of aerodynamics also apply to objects that move through air but do not fly. One can use these principles to explain, for example, how a sailboat sails into the wind.

When the wind puffs the sail out, the sail resembles a cambered airplane wing. The *apparent wind*—the wind measured by an observer on the boat—thus generates a total aerodynamic force that corresponds to the force on a wing. This force can be *resolved into* (represented by) two components relative to the apparent wind: (1) lift, which tends to push the sail in a direction perpendicular to the apparent wind; and (2) drag, which resists the movement of the boat directly against the wind.

The total aerodynamic force can also be resolved into another pair of components: (1) a *driving force* in the sailing direction, and (2) a *heeling force,* which is perpendicular to the driving force. The driving force propels the boat. As the boat moves, the water exerts an aerodynamic force on its hull and *keel.* The keel is the main timber that extends the entire length of the bottom of the boat.



The boat will sail at constant speed when the aerodynamic force generated on the sail is both equal to and opposite the corresponding aerodynamic force that the water exerts on the hull and keel. This condition also has the effect of canceling the heeling force.

NASA/Ames Research Center

Stringlike lines represent airflow in this illustration drawn by a supercomputer. Engineers typically use such *computer simulations* to evaluate proposed designs for an airplane. The engineers then select a design and build a physical model for testing.

How a sonic boom is created

A sonic boom occurs when an airplane flying faster than the speed of sound creates a shock wave. People on the ground hear the boom when the wave reaches them.

WORLD BOOK diagram

Supersonic aerodynamics

Effects of supersonic aerodynamics occur when the airplane flies at speeds greater than the speed of sound. *Supersonic* means *faster than the speed of sound.* Two of the major effects of supersonic aerodynamics are *shock waves* and *sonic booms.* Both are created by pressure disturbances that a moving airplane produces in the air.

These disturbances result from the flow of air around the plane. The disturbances travel away from the plane just as ripples in a pond spread from the spot where a stone falls into the water. Pressure disturbances travel at the speed of sound—about 760 miles per hour (mph), or about 1,225 kilometers per hour (kph), at sea level.

Sound itself is a pressure disturbance, and so some of the disturbances produced by the airplane can be heard. If the plane is flying at less than the speed of sound, the sound of the plane travels ahead of the plane. Thus, people on the ground can hear the plane coming toward them. However, the sound of a plane flying faster than the speed of sound cannot be heard on the ground until the aircraft has passed.

Engineers and pilots use special numbers called *Mach numbers* to describe the speed of planes flying near or above the speed of sound. A Mach number is found by dividing the speed of an airplane by the speed of sound at the plane's altitude. For example, the Mach number of a plane flying at 1,520 mph at sea level would be 2. Modern airliners cruise at an altitude of about 35,000 feet (9,000 meters) and a speed of about Mach 0.80 to Mach 0.85.

Flight that is slightly faster or slower than Mach 1 is known as *transonic* flight. Flight that is significantly slower than Mach 1 is *subsonic.* Flight that is significantly faster than Mach 1 is *supersonic,* and flight at or faster than about Mach 5 is *hypersonic.* Mach numbers are named for Austrian physicist and psychologist Ernst Mach.

Shock waves are pressure disturbances produced by the flight of an airplane at supersonic speed. Because disturbances cannot move ahead of the plane, they build up into shock waves. The waves then attach themselves to the front and rear of the plane. An airplane flying at slightly less than the speed of sound can also produce shock waves. These waves occur because the airflow next to some surfaces of the plane is actually supersonic.

Shock waves create wave drag, thereby increasing the total amount of drag on the plane. A plane designed for transonic and supersonic flight therefore has features that help reduce wave drag. For example, its nose is sharply pointed, and its wings have sharp, thin edges that can knife through the air. The wings may also be angled back from the body of the plane.

Sonic boom. After a supersonic airplane flies overhead, people on the ground may hear a sharp "bang." This sound, called a *sonic boom,* is caused by shock waves from the plane. A plane flying at a supersonic speed sends out at least two shock waves—one from its front and the other from its rear. But the two waves may reach the ground so close together that people hear only one boom. A sonic boom may be strong enough to break windows or damage buildings.

Applying aerodynamic principles

To design an airplane, engineers need to determine how the airflow will interact with the surfaces of the plane. They need to know in detail how strong the air pressure and shear stress will be at various places along the body, the wings, and other parts of the airplane. To gather the information they need, the engineers must study more than the layers of air next to the surfaces. They must investigate the entire *flow field,* the large region of space in which the airflow and the plane will interact. To study flow fields, aircraft design engineers almost always use a combination of two techniques—*wind-tunnel testing* and *computational fluid dynamics.*

Wind-tunnel testing. A wind tunnel is a ground-based facility in which a stream of air is blown at an object at uniform speed. Some wind tunnels are so huge that they can be used to test full-sized experimental airplanes. But most wind tunnels are relatively small facilities that are used to test scaled-down models.

Engineers can obtain much valuable information from wind-tunnel testing. However, the models are expensive to build. Furthermore, as the design evolves, the engineers often must test a large number of different airplane shapes.

Computational fluid dynamics employs *supercomputers,* the fastest and largest computers. In this technique, a supercomputer solves equations describing physical laws that govern what happens at a large number of points in a flow field. The equations contain a huge number of factors that are related to one another in complex ways. Some factors pertain to features of the airplane, such as the sizes and shapes of various parts of the plane. Other factors have to do with flying conditions, including aircraft speed, wind speed, angle of attack, and air density.

The engineers first enter the equations into the supercomputer. Next, they enter the numerical values that apply to the plane they are designing and to the flying conditions. The computer then calculates the corresponding pressures, shear stresses, and other results. These calculations *simulate* (represent) how the airplane

would interact with the air. In many cases, the computer creates a motion picture that shows a few moments of flight. The engineers evaluate the results and change the design as necessary. Allen Plotkin

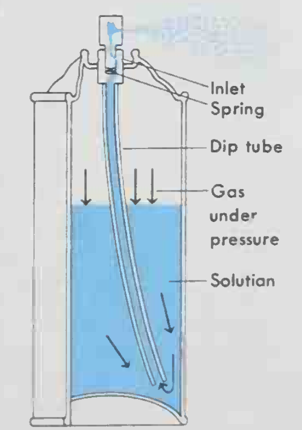
Aerosol, *AIR uh sahl,* is a mixture of extremely small particles and gas. The particles may be liquid droplets or tiny bits of solid material. They are *suspended* (distributed) throughout the gas. Clouds and fog are aerosols that occur naturally. Cans of deodorant and hair spray produce aerosols when used.



Fine solid particles and moisture constantly enter the earth's atmosphere, producing *atmospheric aerosols.* The solid particles include soil and coal dust, smoke, and pollen. Atmospheric aerosols contribute to air pollution. They also reflect some solar radiation back into space, slightly lowering the earth's surface temperature. Light scattered by atmospheric aerosols produces the sky's red glow at sunset.

Containers for manufactured aerosol products are called *aerosol cans.* Within such cans, the product is dissolved in a *propellant,* usually a liquefied gas. The contents of the can are sealed under pressure, and the can is fitted with a release valve. When the valve is opened, the pressurized solution is ejected. The released propellant vaporizes with the product suspended in it, forming an aerosol. Some products in pressurized cans, such as shaving cream and whipped cream, are not aerosols. These foamlike substances consist of gases that are suspended in a liquid base rather than solids or liquids that are suspended in a gaseous base.

Chemicals used as propellants in manufactured aerosols include hydrocarbons, carbon dioxide, and nitrous oxide. Chlorofluorocarbons (CFC's) were also once used extensively as propellants (see **Chlorofluorocarbon**). During the 1970's, however, many scientists became concerned that CFC's were reacting with and diminishing the *ozone layer* in the earth's upper atmosphere. This layer shields the earth's surface from dangerous ultraviolet radiation (see **Ozone**). In 1978, the U.S. government banned the use of CFC propellants. By 1996, most industrialized countries, including the United States, had ended all production of CFC's.

H. Stephen Stoker

An aerosol container sprays out such products as deodorizers and paints in the form of a fine mist. The product is mixed with a liquefied gas, called a *propellant,* and is held in the container under pressure. When the cap of the container is pushed down, the inlet opens and the solution moves through the dip tube. As the solution reaches the opening in the cap, the propellant vaporizes and the particles shoot into the air.

WORLD BOOK diagram

Aerospace industry. See Aviation.

Aerospace medicine is the field of medical science concerned with the effects of flight on human health. It deals with *aviation medicine,* the care of airplane crews and passengers; and *space medicine,* the care of astronauts. Doctors and scientists in this field try to increase the job performance and safety, as well as the health, of people who fly.

Aviation medicine. There are many common stresses of air travel. They include motion sickness, noise, vibration, changes in oxygen levels, and rapid changes in speed and atmospheric pressure.

An important stress in fighter aircraft is a rapid upward acceleration. This movement can cause blood to be *pooled,* or concentrated, in the lower parts of the body. The flow of blood to the heart may then be insufficient for the heart to maintain adequate circulation to the brain, causing unconsciousness. As a result, fighter pilots must wear special trousers called *G suits* that squeeze blood out of the legs and back to the heart.

Doctors who specialize in aviation medicine are called flight surgeons. Flight surgeons help to design equipment and develop crew selection and training programs. Other areas of aviation medicine include investigating accidents, training crews for survival after crashing, and transporting sick or injured people by air.

Space medicine. During space travel, *weightlessness* (freedom from the pull of gravity) can cause several disorders. These include motion sickness, *disorientation* (loss of a sense of direction), and a shift of blood and other fluids from the feet and legs to the chest and head. Weightlessness also can cause the loss of bone and muscle tissue in the feet and legs. This condition probably occurs because the bones and muscles no longer need to work against the pull of gravity. Researchers are seeking a combination of exercises, drugs, and special diets that will reduce bone and muscle loss.

Another hazard of space flight is radiation from the sun and other objects in space. Being exposed to radiation increases a person's chances of developing leukemia and other cancers. Astronauts exposed to more than a certain amount of radiation would be grounded. Today's spacecraft have too little protection against radiation for long-duration manned flights into *deep space* (space beyond the earth and the moon).

Some scientists have suggested that the most serious problem for astronauts on long missions could be psychological. Space travelers have found that after 30 days of being confined together in a small space on a flight

scheduled to last many months, they develop an intense dislike for each other and a strong desire to go home.

Aeschylus, *EHS kuh luhs* (525-456 B.C.) was the earliest writer of Greek tragedy whose plays exist in complete form. He wrote more than 80 plays, of which seven survive. These seven plays reveal a deeply patriotic and religious artist who brought Greek tragedy to maturity. Before Aeschylus, tragedies had a single actor who could only respond to the questions or suggestions of the chorus. Aeschylus increased the number of actors to two, which created dialogue that permitted interaction between characters.

Aeschylus's plots are simple. Most of them center on a conflict between an individual's will and the divine powers that rule the world. Aeschylus wrote tragedy in the grand manner, with a richness of language and complexity of thought that only the English playwright William Shakespeare has rivaled. Aeschylus's greatest work is the *Oresteia* (458 B.C.), which consists of three plays forming one drama. They are *Agamemnon, The Libation Bearers,* and *The Eumenides* (The Furies). In these plays, Aeschylus turned the violence after the return of King Agamemnon from Troy into a drama about the reconciliation of human suffering with divine power. Aeschylus's other surviving plays are *The Persians* (472), *Seven Against Thebes* (467), *The Suppliants* (463?), and *Prometheus Bound,* which was probably written late in Aeschylus's life. Aeschylus was born into a prominent family in Eleusis, near Athens.

Aesculapius. See Asclepius.

Aesop's fables, *EE sahps,* are a collection of stories attributed to a Greek slave named Aesop, who died about 565 B.C. Like all fables, each of these tales teaches a moral and offers useful advice. Most of the characters in Aesop's fables are animals that talk and act like humans. They show the failings and virtues of human nature in a simple, humorous way. Each fable ends with a proverb that sums up the fable's moral and advice.

The best-known of Aesop's fables is probably "The Tortoise and the Hare." It tells about a race between a slow tortoise and a swift hare. Halfway through the race, the hare is so far ahead and so confident of victory that he takes a nap. The tortoise plods along steadily and eventually passes the hare, who awakens and sees his slow opponent crossing the finish line. The proverb "Slow and steady wins the race" sums up the moral of this story, teaching that persistence can be more important than speed.

Another favorite fable, "The Ant and the Grasshopper," illustrates the value of hard work and preparation for the future. In this fable, the grasshopper frolics all summer, while the ant stores food. When winter comes, the ant has plenty to eat, but the grasshopper starves.

Aesop's fables have provided numerous popular expressions. For example, an enemy who pretends to be a friend is sometimes called "a wolf in sheep's clothing." This expression comes from the fable in which a wolf disguises himself in a sheepskin. The wolf then moves undetected among a herd of sheep and kills them for food. However, the shepherd also mistakes the wolf for a sheep and kills him for supper.

No one knows how many of the stories attributed to Aesop were actually composed by him. Some of the fables originated from more ancient sources, and Aesop may have been responsible only for retelling them and making them popular.

For many years, Aesop's fables were handed down orally from generation to generation. About 300 B.C., an Athenian politician named Demetrius of Phaleron gathered about 200 of them into a collection called *Assemblies of Aesopic Tales.* This collection was translated into Latin about 300 years later by Phaedrus, a freed Greek slave. About A.D. 230, the Greek writer Valerius Babrius combined Aesop's fables with some from India and translated all of them into Greek verse. Since then, other writers have retold the fables and expanded their meaning, but the tales have never lost their original charm and simplicity.

Aesthetics, *ehs THEHT ihks,* also spelled *esthetics,* is the study of theories that apply to the arts in a broad and fundamental way. People think about aesthetics when they ask why some things are beautiful and some are not, or whether there are basic rules for creating or interpreting good paintings, poems, and music.

Aestheticians study the arts in general. They compare arts from different cultures and from different periods of history, in order to organize our knowledge of them systematically. For many years, the study of beauty was regarded as the central problem of aesthetics. Now the subject has broadened to include many other aspects of art. Aestheticians try to understand how art is related to what people feel, to what they learn, and to the cultures in which they live. To gain this understanding, they collect, organize, and interpret information about the arts and aesthetic experience. Aestheticians try to find whether there are standards of art criticism. This helps people appreciate different kinds of art and judge them intelligently.

In addition to studying theories about works of art, aestheticians want to understand artists and audiences. They can understand art better if they have learned how artists imagine, create, and perform, and what makes artists' activities different from the work of nonartists. They also try to understand what happens to people's feelings when they experience art. Aestheticians study how art affects people's moods, beliefs, and values.

Aesthetics is the youngest branch of philosophy to be given its own name, which was first used in the late 1700's. But philosophers from the ancient Greeks to the present day have discussed the philosophy of art. Almost all of them have talked about whether art is good for people and for society. Some point out that art can have dangers as well as benefits, and a few argue that art and artists are so disruptive that they threaten the social order. But most philosophers believe art is good because it allows us to express our emotions, teaches us

about ourselves and the world, or communicates the traditions of different times and cultures.

Aestheticians use art history to understand the art of previous times. They use the psychology of art to learn how our senses interact with our imagination and understanding when we experience art. Art criticism serves as a guide to enjoy each individual work of art. The social sciences, such as anthropology and sociology, help aestheticians understand how creating and appreciating art relate to other human activities. The social sciences also indicate how art varies in relation to physical, social, and cultural environments. Anita Silvers

Affenpinscher, *AH fuhn PIHN shuhr,* is a small, shaggy, black dog. It weighs about 8 pounds (3.6 kilograms), and stands only 10 inches (25 centimeters) high. It has bushy eyebrows that hang down over its eyes. Tufts of hair stick out all over its face, and it has a mustache. The name *affenpinscher* comes from the German words meaning *monkey terrier.* The affenpinscher is bold, quick on its feet, and playful.

Affidavit, *AF uh DAY viht,* in law, is a written or printed statement of facts sworn to, or affirmed, before a court bailiff, a notary public, or any other person qualified to administer an oath. The person who swears to the truth of an affidavit usually must sign it.

In the United States, affidavits can be introduced as evidence in a few stages of legal proceedings. But judges and lawyers generally consider affidavits less reliable evidence than oral testimony given by a witness in open court. The reason is that an affidavit may be signed and sworn to without the presence of an adversary to contradict it if it misstates the facts. Oral testimony given in open court may be questioned by the attorney for the opposing party.

Affidavits are widely used in preliminary legal proceedings. For example, when the plaintiff files a written complaint to start a lawsuit, the law may require that the plaintiff include an affidavit of the truth of the charges.

Affirmative action refers to policies aimed at increasing the numbers of people from certain social groups in employment, education, business, government, and other areas. In the United States, these groups are women and such minorities as African Americans, Asian Americans, Hispanic Americans, American Indians, disabled people, and Vietnam veterans. In general, affirmative action is intended to benefit groups that are thought to have suffered from discrimination. But critics argue that some groups benefit from affirmative action as a result of their political influence.

Different affirmative-action programs have different features. Some seek only to remove barriers so that all people may compete equally. Others use numerical goals called *quotas* to ensure that women or minorities are included in preset proportions. Programs using quotas may prefer members of certain groups.

For federal contracts, the term *affirmative action* was first used in an order issued by President John F. Kennedy in 1961. That and other early federal orders required businesses with U.S. government contracts to treat their employees without regard to race, ethnic origin, religion, or gender. Later, the government asked these businesses to consider the race and gender of their employees to ensure that the mix of people on their staffs reflected the mix in the local work force. Also, a share of federal contracts were set aside for businesses owned by women or minorities. Many state and local governments, as well as many businesses and schools, created their own affirmative-action programs.

Since the 1970's, controversy over affirmative action has grown. People disagree about how to achieve the goal of nondiscrimination. Some claim temporary preferences are necessary to achieve equality. Others believe quotas and other affirmative-action policies unfairly affect the right of people to be treated according to their abilities. People also disagree about which groups are entitled to affirmative action and for how long.

In 1995, the United States Supreme Court ruled that a federal program requiring preference based on a person's race is unconstitutional unless the preference is designed to make up for specific instances of past discrimination. This meant that affirmative action could no longer be used to counteract racial discrimination by society as a whole, but must be aimed at eliminating specific problems. In 1989, the court had made a similar decision regarding state and local programs.

In 1996, voters in California approved Proposition 209, which banned the use of racial or gender preferences in public hiring, contracting, and education. Voters in Washington state approved a similar measure, Initiative 200, in 1998. At some universities where affirmative action has been abolished, new admissions policies have been established to ensure diversity. Some university systems now use a percentage formula based on high-school class ranking. Also during the 1990's, federal courts ruled that affirmative action programs in a number of states discriminated against nonminorities. George R. LaNoue

Afghan hound, *AF guhn,* is a dog known for its speed and agility. It has been used for hunting gazelles, hares, and snow leopards in Afghanistan for hundreds of years. The Afghan hound has long ears, large feet, and a heavy coat of long, silky hair. It can be any of many colors. It stands about 27 inches (69 centimeters) high at the shoulder and weighs about 50 to 60 pounds (23 to 27 kilograms). The Afghan hound moves with its head and tail held high. No one knows just where or when the Afghan originated. See also **Dog** (picture: Hounds).

AP/Wide World

Kabul, Afghanistan's capital and largest city, has both traditional and modern buildings. Traditional mud-brick dwellings, such as those on the hillside, are found throughout Afghanistan. Some modern buildings rise in downtown Kabul. Parts of the city are being rebuilt after decades of war.

Afghanistan

Afghanistan, a nation in southwestern Asia, has towering mountains, scorching deserts, fertile valleys, and rolling plains. Afghanistan is surrounded by six other countries and so does not have a seacoast. The country is bordered by Turkmenistan, Uzbekistan, and Tajikistan on the north, China on the far northeast, Pakistan on the east and south, and Iran on the west.

Afghanistan is one of the world's least developed countries. Most Afghan workers farm the land, and many use old-fashioned farming tools and methods. Some of the people are nomads, who roam the country with their herds of sheep or goats. Kabul is the capital and largest city of Afghanistan.

Almost all the people of Afghanistan are Muslims. The religion of the Muslims, Islam, is the chief common link among them. The population of Afghanistan consists of about 20 ethnic groups, most of which are divided into several tribes. Most of the ethnic groups have distinct languages and cultures. The variety of ethnic groups has made it difficult for Afghanistan to develop into a unified, modern nation.

Afghanistan has a long and troubled history. In early days, Persians, Greeks, Mongols, and other peoples conquered the region. In modern times, Afghanistan has continued to suffer foreign interference. The Soviet Union sought to occupy Afghanistan in a war that lasted from 1979 to 1989.

In the 1990's, a conservative Islamic group called the Taliban came to power. The Taliban allowed international terrorist organizations to run training camps in Afghanistan. After terrorist attacks against the United States in 2001, the United States and anti-Taliban forces within Afghanistan drove the Taliban from power. A transitional government was set up to rule the country.

Facts in brief

Capital: Kabul.

Official languages: Pashto (also called Pakhto) and Dari.

Official name: *Da Afghanistan Dowlat* (in Pashto) or *Dowlati Afghanistan* (in Dari), both meaning State of Afghanistan.

Area: 251,773 mi² (652,090 km²). *Greatest distances*—east-west, 820 mi (1,320 km); north-south, 630 mi (1,012 km).

Elevation: *Highest*—Nowshak, 24,557 ft (7,485 m) above sea level. *Lowest*—In Sistan Basin, 1,640 ft (500 m) above sea level.

Population: *Estimated 2002 population*—24,977,000; density, 99 persons per mi² (38 persons per km²); distribution, 80 percent rural, 20 percent urban. *1979 census*—13,051,358.

Chief products: *Agriculture*—barley, corn, cotton, fruits, Karakul skins, mutton, nuts, rice, vegetables, wheat, wool. *Manufacturing*—jewelry, leather goods, rugs. *Mining*—coal, lapis lazuli, natural gas.

Money: *Basic unit*—afghani. One hundred pule equal one afghani.

A *jirga* (council) is a traditional Afghan community meeting. This jirga near Khowst, in eastern Afghanistan, met in 2002 to choose delegates to send to a national *loya jirga* (grand council) in Kabul.

Government

In the late 1990's, the Taliban controlled most of Afghanistan, including Kabul. The Taliban imposed their harsh interpretation of Islamic law on the country. However, few nations recognized the Taliban government as the legal government of Afghanistan.

The United States and its Afghan allies drove the Taliban from power in 2001. The United Nations then brought together the leaders of Afghanistan's main ethnic and regional groups, who organized a temporary government. These leaders also developed a plan for creating a permanent, more democratic government. Hamid Karzai, head of the Popalzai, an important clan of the Pashtun ethnic group, became head of the temporary government.

In June 2002, Afghan leaders held a *loya jirga* (grand council) to create a transitional government. Loya jirgas are held at times of crisis or when major political or social changes need consideration. Loya jirgas attempt to include representatives of all of Afghanistan's many regional and ethnic groups. In 1964, Afghan women attended a loya jirga for the first time. Afghan tribes and communities often hold smaller *jirgas* (councils) to decide matters of local importance. Local jirgas include all of a single community's adult men or the leaders from several neighboring communities.

In 2002, the loya jirga created a transitional government to lead the country for up to two years. During that time, it would work to establish a commission to create a new constitution and then hold democratic elections for a permanent government. The loya jirga chose Karzai as president of the transitional government. To gain national support for the government, Karzai selected Afghans from a variety of regions and ethnic groups to serve in his cabinet.

People

Ancestry. Most Afghans are a blend of early peoples who came to the country as invaders or settlers. These groups included Aryans, Persians, Arabs, Turkish-speaking people from central Asia, Mongolians, and people from the Xinjiang region of western China.

Ethnic groups and languages. Afghanistan has about 20 ethnic groups, most of which have their own language and culture. Most ethnic groups consist of several tribes, many of which speak their own dialect of the ethnic language. Many Afghans feel greater loyalty to their ethnic group or tribe than to their country.

The largest ethnic groups are the Pashtuns (or Pakhtuns) and the Tajiks. *Pashtuns* and *Pakhtuns* are also spelled *Pashtoons* and *Pakhtoons.* The Pashtuns and Tajiks make up more than 60 percent of the population. Most Pashtuns live in the southeast, near the Pakistan border. Their language, *Pashto* or *Pakhto,* is one of Afghanistan's two official languages. Most Tajiks live in northeastern Afghanistan and speak *Dari,* the other official language. Dari is also known as Afghan Persian. Most of the country's other ethnic groups speak Dari as either their first or second language.

Way of life. Most of Afghanistan's rural people live in homes made of sun-dried mud bricks. City dwellers live in homes and apartment buildings made of baked brick, concrete, or both. Most of the country's nomadic and seminomadic people live in tents made of goat hair.

Most Afghans wear traditional clothing. In winter, the people wear a heavy coat made of sheepskin, quilted

Symbols of Afghanistan. Afghanistan's flag has black, red, and green vertical stripes and the nation's coat of arms in the center. The coat of arms bears four Arabic inscriptions: at the top, *There Is No God but Allah and Muhammad Is the Prophet of Allah;* near the top, *God Is Great;* near the bottom, the Islamic year *1380* (2001-2002 in the Gregorian calendar); and at the bottom, *Afghanistan.*

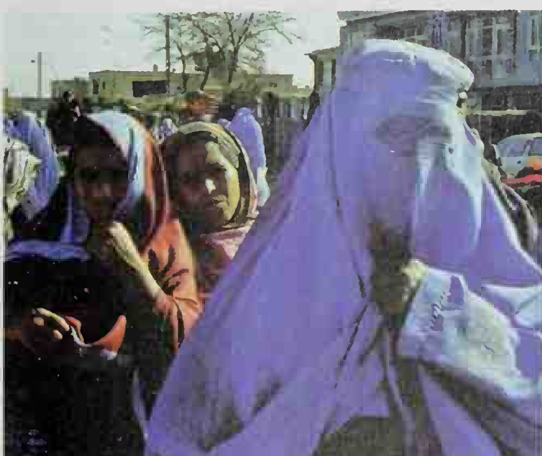
Islam greatly influences family and community relationships and almost all other aspects of Afghan life. This beautiful blue *mosque* (Islamic house of worship) is in Mazar-e Sharif.

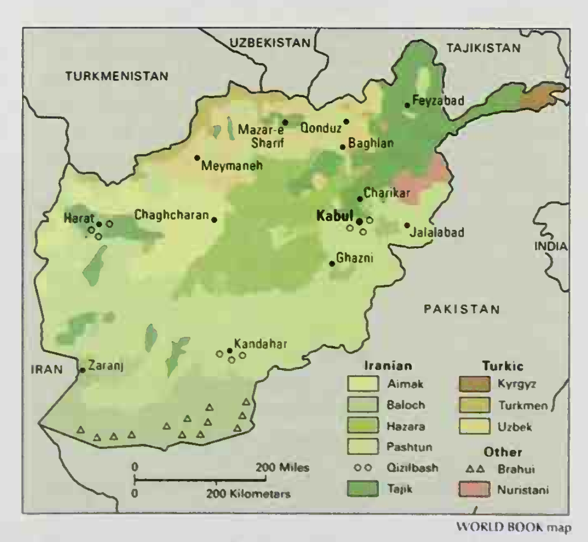
fabric, or felt. Many rural men wear a turban, which may be tied in a certain way to indicate their ethnic group. Most Pashtun women wear a *burqa,* also called a *chadri,* which is a full-length hooded garment that covers the body from head to toe. The Pashtuns believe a woman must not be seen by any men outside of her family. Some rural women in Afghanistan cover their heads with a shawl.



Afghans serve flat loaves of whole-grain, sourdough bread at every meal. They also enjoy vegetables, yogurt, chicken, beef, mutton, and rice. Popular desserts include nuts and fruits. Tea is the favorite drink.

Women have traditionally played a secondary role in Afghan society. Their opportunities for education and careers have been limited, especially in rural areas. Men dominate women in many ways. For example, some Afghan tribes do not allow women to leave their homes without a male relative.

During the 1900's, several Afghan governments attempted to give women more rights. In 1964, for example, a new constitution gave Afghan women equal status with men, and the social and economic position of some women improved. However, most women in rural areas never gained more rights.



In the 1990's and early 2000's, the Taliban greatly limited the freedom of women. For example, the Taliban required all women to cover themselves completely when in public. They also made it illegal for women to work outside their homes. Women who violated Taliban laws were punished severely.

After the Taliban were driven from power in 2001, many Afghan women hoped to reclaim their lost rights. In 2002, several women played significant roles in the national council that created a transitional government and helped decide the country's future.

WORLD BOOK map

Afghanistan's major ethnic groups inhabit various parts of the country. The map key arranges the ethnic groups by their language types. For example, the language spoken by the Pashtuns is an Iranian language, but that spoken by Uzbeks is Turkic. Stripes indicate areas shared by more than one ethnic group.

Goat herders lead their herd over an arid mountain path. Afghanistan's economy depends heavily on agriculture. Many of the country's farmers practice sheep and goat herding.

Religion. About 99 percent of all Afghans are Muslims. Their religion strongly influences family and community relationships and most other aspects of life. Almost every Afghan village or nomadic group has a religious leader called a *mullah.* Mullahs lead prayer services and educate the young. They sometimes have great influence in their communities.

Education. Most of Afghanistan's people 15 years of age or older cannot read and write. For the country's literacy rate, see **Literacy** (table: Literacy rates for selected countries). Many children cannot attend school because the country does not have enough schools or teachers. This lack of educational facilities is due largely to the upheaval caused by decades of war. Afghanistan has two universities—Kabul University and Ningrahar University in Jalalabad.

The arts. Because most of the people of Afghanistan cannot read and write, folklore, folk songs, and folk dances play an important part in Afghan life. They enable the people to pass their values and traditions on from one generation to the next. The *attan* (also spelled *atan*) is an energetic folk dance. Pashtuns dance the attan at weddings and other community celebrations.

Recreation. Afghans enjoy sports and games, such as soccer, volleyball, and basketball. Many men in Afghanistan like to hunt, and some of them use the famous Afghan hounds as hunting dogs. Men of the northern plains play a game called *buzkashi.* In the game, dozens of horsemen try to grab a headless calf and carry it across a goal.

The land and climate

Afghanistan is made up of three main land regions. These regions are, from north to south: (1) the Northern Plains, (2) the Central Highlands, and (3) the Southwestern Lowlands.

The Northern Plains stretch across northern Afghanistan and consist of mountain plateaus and rolling hills. The soil is fertile in the Northern Plains but can be cultivated only where water is available. Large irrigation systems have been built along the Harirud, Helmand, Qonduz, and other rivers. Nomadic and seminomadic people raise sheep and goats on the vast grasslands.

Temperatures in the Northern Plains of Afghanistan average about 38 °F (3 °C) in January and approximately 90 °F (32 °C) in July. The average annual precipitation in the region totals about 7 inches (18 centimeters).

The Central Highlands cover about two-thirds of Afghanistan. They consist of the towering Hindu Kush mountain range and its branches. Snow-capped peaks rise about 25,000 feet (7,620 meters) along the Pakistani border in the east. The range gradually descends to a rolling plain in the southwest. Most Afghans live in the high, narrow valleys of the Hindu Kush.

The Central Highlands have an average temperature of about 25 °F (–4 °C) in January and about 75 °F (24 °C) in July. The region receives about 15 inches (38 centimeters) of precipitation yearly.

The Southwestern Lowlands lie in southwestern Afghanistan and consist mainly of desert or semidesert land. The region is crossed by the Helmand River, which flows from the Hindu Kush to the Sistan Basin on the Iranian border. The basin has several slightly salty lakes and marshes. Barley, corn, fruits, and wheat are grown in the Helmand Valley.

Temperatures in the lowlands of Afghanistan average about 35 °F (2 °C) in January and about 85 °F (29 °C) in July. The average annual precipitation ranges from 2 to 9 inches (5 to 23 centimeters).

Economy

Afghanistan's economy once benefited from the country's location along the Silk Road and other ancient trade routes. As these routes died out, the country became isolated. In the mid-1900's, Afghan governments attempted to develop the country's economy and to improve educational opportunities. But decades of war and internal struggles at the end of the 1900's reversed most of these advances. A severe drought in the late 1990's and early 2000's further weakened Afghanistan's economy. However, economic aid flowed into the country following the defeat of the Taliban in 2001.

Agriculture. About 85 percent of all Afghan workers earn their living in agriculture. Wheat is the chief crop of Afghanistan. Other crops include barley, corn, cotton, fruits, nuts, rice, sugar beets, and vegetables. Production is limited by a shortage of modern machinery, fertilizer, and high-quality seeds.

During the late 1900's, Afghanistan became one of the world's leading producers of opium, which is used to make the illegal drug heroin. Many Afghan farmers raised opium poppies because it was more profitable than growing wheat and other food crops. In 2000, the Taliban began enforcing a strict ban on poppy farming, but the practice resumed after the Taliban were driven from power in 2001. The governments that have ruled Afghanistan since then have also tried to stop farmers from growing opium poppies.

Afghanistan's nomadic and seminomadic people raise most of the country's livestock. The chief livestock products are dairy items, mutton, wool, and animal hides. The skins of Karakul sheep, a fat-tailed sheep known for its silky pelt, are especially valuable.

Mining. Afghanistan is rich in minerals, but most of the deposits are largely undeveloped. In the 1960's, large deposits of natural gas were discovered in Afghanistan. Since then, the production of natural gas

has become an important part of the nation's economy. Afghanistan also produces some coal, copper, gold, and salt. The country has huge deposits of iron ore, but because of Afghanistan's rugged terrain and frequent conflicts, they remain undeveloped.

Afghanistan has deposits of the world's finest lapis lazuli, a valuable azure-blue stone. Other gemstones mined in the country include amethysts and rubies.

Manufacturing. Afghanistan has little industry. Skilled craftworkers in their homes or small shops make gold and silver jewelry, leather goods, rugs, and other handicraft items. A few mills produce textiles, and small factories turn out such products as cement, matches, and processed foods.

International trade. Afghanistan's leading exports are cotton, fruits and nuts, natural gas, rugs, and Karakul sheep skins. Imports include machinery, motor vehicles, petroleum products, and textiles. Afghanistan conducts its international trade mainly over land, through the neighboring countries of Iran and Pakistan.

Transportation and communication. Afghanistan has about 11,700 miles (18,800 kilometers) of roads. However, decades of war heavily damaged most paved roads, making many of them unusable. The country has no railroads.

Afghanistan's most famous transportation route is the Khyber Pass, which crosses the border between Afghanistan and Pakistan. The pass cuts through the Safid Kuh mountains, which are part of the Hindu Kush range. Conquerors, such as Alexander the Great of Macedonia, crossed the pass to invade South Asia. The Khyber Pass has been an important trade route for centuries. See Khyber Pass.

Several newspapers are published in Afghanistan. The country has one national television station and one national radio station. Both stations broadcast from Kabul.

History

Prehistoric hunting people lived in what is now Afghanistan as early as 100,000 years ago. After many thousands of years, the people learned how to farm and to herd animals. Agricultural villages then developed. By about 4000 to 2000 B.C., a number of these villages had grown into small cities.

Early invasions. About 1500 B.C., the Aryans, a central Asian people, invaded the region. They killed many of the area's inhabitants and intermarried with others. In the mid-500's B.C., Persians invaded northern Afghanistan, a region then called Bactria. The Persians ruled Bactria until about 330 B.C., when Greeks and Macedonians led by Alexander the Great conquered the region and much of the rest of Afghanistan.

About 246 B.C., the Bactrians revolted. They eventually conquered Bactria and other parts of Afghanistan. They formed a kingdom that lasted about 150 years, until the Kushans of central Asia seized Afghanistan. Sasanians from Persia invaded in the A.D. 200's, and White Huns from central Asia defeated the Kushans and Sasanians in the 400's.

The coming of Islam. Arab Muslim armies swept into parts of what is now Afghanistan during the late 600's. Three Muslim dynasties—the Tahirid, the Samanid, and the Saffarid—controlled much of the region during the 800's and 900's. Under these dynasties,

The Anglo-Afghan wars of the 1800's resulted largely from the United Kingdom's desire to protect its Indian empire. This photograph shows British troops at a fort in Kabul in 1879.

most local inhabitants became Muslims.

Turkic-speaking peoples from eastern Persia and central Asia ruled Afghanistan from about 900 to 1200. Afghanistan was conquered by Mongols led by Genghis Khan in the 1200's and led by Timur, also called Tamerlane, in the 1300's. Safavids from Persia and Mughals from India struggled for control of Afghanistan from the mid-1500's to the early 1700's.

United Afghanistan. In 1747, Ahmad Khan came to power. He took the title *shah* (king) and adopted the name *Durrani* (Pearl of the Age). Ahmad Shah Durrani united the many Afghan tribes for the first time, marking the beginning of modern Afghanistan. He gained control of territory stretching far beyond the country's current borders.

Ahmad Shah was succeeded by his son Timur Shah. Around 1775, Timur Shah moved the capital from Kandahar to Kabul. Timur Shah and his successors struggled to keep the Afghan tribes united and lost control of most of the territory beyond the current borders of Afghanistan.

In 1819, civil war broke out among rival tribes that wanted to rule the country. The war lasted until 1826, when Dost Muhammad Khan gained control. He took the title of *amir* (prince). Dost Muhammad's descendants ruled the country for the next 150 years.

The Anglo-Afghan wars. During the 1800's, the United Kingdom and Russia competed for control of Afghanistan. Russia wanted an outlet to the Indian Ocean and began to expand toward Afghanistan. The United Kingdom wanted to protect its empire in India, which was threatened by Russia's expansion. In 1839, British troops invaded Afghanistan to reduce Russia's influence in the region. The invasion set off the First Anglo-Afghan War, which lasted until the British withdrew in 1842. Russian influence near Afghanistan increased during the mid-1800's.

In 1878, the United Kingdom invaded the country again, starting the Second Anglo-Afghan War. The British found it difficult to establish control of Afghanistan. In 1880, Abdur Rahman Khan became amir. The British agreed to recognize his authority over the country's internal affairs. In return, Abdur Rahman accepted the United Kingdom's control of Afghanistan's foreign relations. During his reign, Abdur Rahman worked to

strengthen the national government and to reduce the power of tribal leaders. After he died in 1901, his policies were continued by his son Habibullah Khan.

Independence. Early in 1919, Habibullah Khan was assassinated. One of his sons, Amanullah Khan, then became amir and attacked British troops in India, beginning the Third Anglo-Afghan War. The United Kingdom had just finished fighting in World War I (1914-1918). It decided to end its involvement in Afghanistan rather than fight another war. In August 1919, Afghanistan became fully independent.

Amanullah began many reforms to modernize Afghanistan, rapidly sweeping away centuries-old traditions and customs. The nation's first constitution was adopted in 1923, and Amanullah changed his title from amir to shah in 1926. But tribal and religious leaders resisted the reform movement and forced Amanullah Shah to give up the throne in 1929.

Late in 1929, Muhammad Nadir Shah became king. In 1931, Afghanistan adopted a new constitution. Under the new Constitution, Nadir Shah began a program of gradual reform. But he was assassinated in 1933, before many of the reforms were begun. Muhammad Zahir Shah, Nadir Shah's son, then became king.

The mid-1900's. By the early 1950's, Afghanistan had developed good relations with the United States and many Western European nations. But the Afghans feared the intentions of the Soviet Union, their country's powerful Communist neighbor. In 1953, Muhammad Daoud Khan, the king's cousin and brother-in-law, took control of the government and made himself prime minister. Under Daoud, Afghanistan took no side in the Cold War, a period of hostility between Communist and non-Communist nations, and it received aid from both the United States and the Soviet Union.

Border disputes with Pakistan and other problems led to pressures that forced Daoud to resign in 1963. In 1964, under the leadership of Zahir Shah and Western-educated scholars and thinkers, Afghanistan adopted a constitution that provided for a democratic government. But many problems arose. Zahir Shah and the legislature could not agree on the role of political parties within the reform program. Parliament often deadlocked on key issues. In addition, the Afghan people had little experience with, or understanding of, democratic government. As a result, the new democratic system failed to bring about the progress that the framers of the Constitution had hoped for.

In 1973, Daoud led a military revolt that overthrew Zahir Shah. Afghanistan's military, aided by Afghan Communists, took control of the government and established the Republic of Afghanistan with Daoud as president and prime minister.

The Soviet invasion. In 1978, rival left-wing military leaders and civilians in Afghanistan staged another revolt, during which Daoud was killed. This group, which received much financial and military aid from the Soviet Union, took control of the government and established policies that had some features of Communism.

Many in Afghanistan opposed the new government. They believed the government's policies conflicted with teachings of Islam. In addition, they resented Soviet influence on the government. Large numbers of Afghan people joined in a rebellion against the government shortly after it came to power. Widespread fighting broke out between the rebels, who called themselves *mujahideen* (holy warriors), and government forces.

The Soviet Union became concerned that the rebels might defeat the Afghan government forces. In 1979 and 1980, the Soviet Union sent thousands of troops to join the fight against the rebels. The Soviets had far better equipment than their opponents. But the rebels, supplied by countries opposed to the Soviet Union, used guerrilla tactics to overcome the Soviet advantage. The Soviets and Afghan government forces bombed many villages.

In 1988, the Soviet Union began withdrawing its troops from Afghanistan. The withdrawal was completed in February 1989. But the fighting between the mujahideen and government forces continued until 1992, when the rebels overthrew the government.

Afghanistan under the Taliban. After 1992, Afghanistan had several governments made up of various combinations of mujahideen groups. Continued fighting among the groups prevented the establishment of a stable government. In the mid-1990's, a new group,

AP Wide World

Soviet troops retreated from Afghanistan in 1989. The Soviet Union invaded Afghanistan in 1979 and 1980 to support the Communist government there. Despite their superior military strength, the Soviets failed to defeat the Afghan rebels, known as *mujahideen.*

Hamid Karzai, *left,* led Afghanistan after the fall of the Taliban in 2001. The former king of Afghanistan, Muhammad Zahir Shah, *right,* supported Karzai and helped unify the country.

a conservative Islamic organization known as the Taliban, rose to power.

Pashtun religious students who had fled to Pakistan during the Soviet invasion started the Taliban movement. The Taliban were supported by Pakistan's military and by militant Arab Islamic groups. By the late 1990's, the Taliban gained control of most of Afghanistan. They established a Council of Ministers to rule the country.

The Taliban imposed their strict interpretation of Islam on the nation. For example, they banned television, popular music, and most other modern forms of entertainment, and they established rules for dress and grooming. All women were forced to cover themselves completely when in public, and men were required to grow beards. The Taliban also prohibited girls from attending school and forbade women from working outside the home.

The Taliban destroyed many artifacts of the country's heritage because they claimed they were anti-Islamic. For example, they demolished two ancient statues of Buddha carved into a mountainside near Bamian, Afghanistan. The Taliban also destroyed many works of art in the country's museums.

Through the decades of war in the late 1900's, millions of Afghans fled to neighboring Pakistan and Iran, and thousands more became refugees in their own country. Years of drought in the late 1990's and early 2000's left many Afghans in danger of starvation.

Recent developments. In 2001, members of a terrorist organization called al-Qa'ida attacked the World Trade Center in New York City and the Pentagon Building near Washington, D.C. (see **September 11 terrorist attacks**). The United States accused the Taliban of harboring and assisting al-Qa'ida, which was led by the Saudi-born millionaire Osama bin Laden. The United States demanded that the Taliban arrest bin Laden and the other terrorists and shut down their training camps. The Taliban refused to do so, and the United States and its allies launched a military campaign against the Taliban.

The campaign included air strikes in support of Afghan rebels who opposed the Taliban. This support enabled the rebels to drive the Taliban from power in late 2001. Meanwhile, the United Nations brought together representatives of Afghanistan's leading groups to discuss the formation of a new and stable national government. The conference agreed on a plan that included the appointment of a temporary government and the eventual creation of a new constitution and a democratically elected government.

An international peacekeeping force arrived in Kabul in late 2001 and early 2002. In the absence of a strong central government, however, warlords and tribal groups continued to compete for territory and power. Also, small groups of Taliban and al-Qa'ida forces continued to battle U.S. and allied troops.

In April 2002, the former king of Afghanistan, Muhammad Zahir Shah, returned to the country. He did not resume his role as king but attended a *loya jirga* (grand council) of Afghan leaders. In June, the loya jirga met in Kabul and chose Hamid Karzai, leader of the Popalzai clan, as the country's transitional president.

Nairobi, the capital of Kenya

The vast continent of Africa is a land of striking contrasts. Regions of untouched natural beauty and modern cities are both part of the African landscape. Old and new ways of life exist throughout Africa, and hundreds of ethnic groups have contributed to a rich cultural heritage.

Africa

Africa is the second largest continent in area and in population. Only Asia covers a larger area and has more people. Africa covers about a fifth of the world's land area and has about an eighth of its people.

Africa is divided into 53 independent countries and several other political units. The largest country, Sudan, has an area of 967,500 square miles (2,505,813 square kilometers). The smallest country, Seychelles, has a land area of only 176 square miles (455 square kilometers). The most heavily populated African nation, Nigeria, has more than 125 million people. However, about two-fifths of all African countries have fewer than 5 million people each.

The African continent is an immense plateau, broken by a few mountain ranges and bordered in some areas by a narrow coastal plain. It is a land of striking contrasts and great natural wonders. In the tropical rain forests of western and central Africa, the towering treetops form a thick green canopy. The world's largest desert, the Sahara, stretches across northern Africa. It covers an area almost as large as the entire United States. Africa also has the world's longest river—the Nile. It flows more than 4,000 miles (6,400 kilometers) through northeastern Africa. Much of the continent is grassland. Elephants, giraffes, lions, zebras, and many other animals live in the grasslands located in eastern and southern Africa.

The African people belong to several population groups and have many cultural backgrounds. In the north, for example, most of the people are Arabs. South of the Sahara, where most Africans live, blacks form the great majority of the population. But they are divided into over 800 *ethnic groups,* each with its own lan-

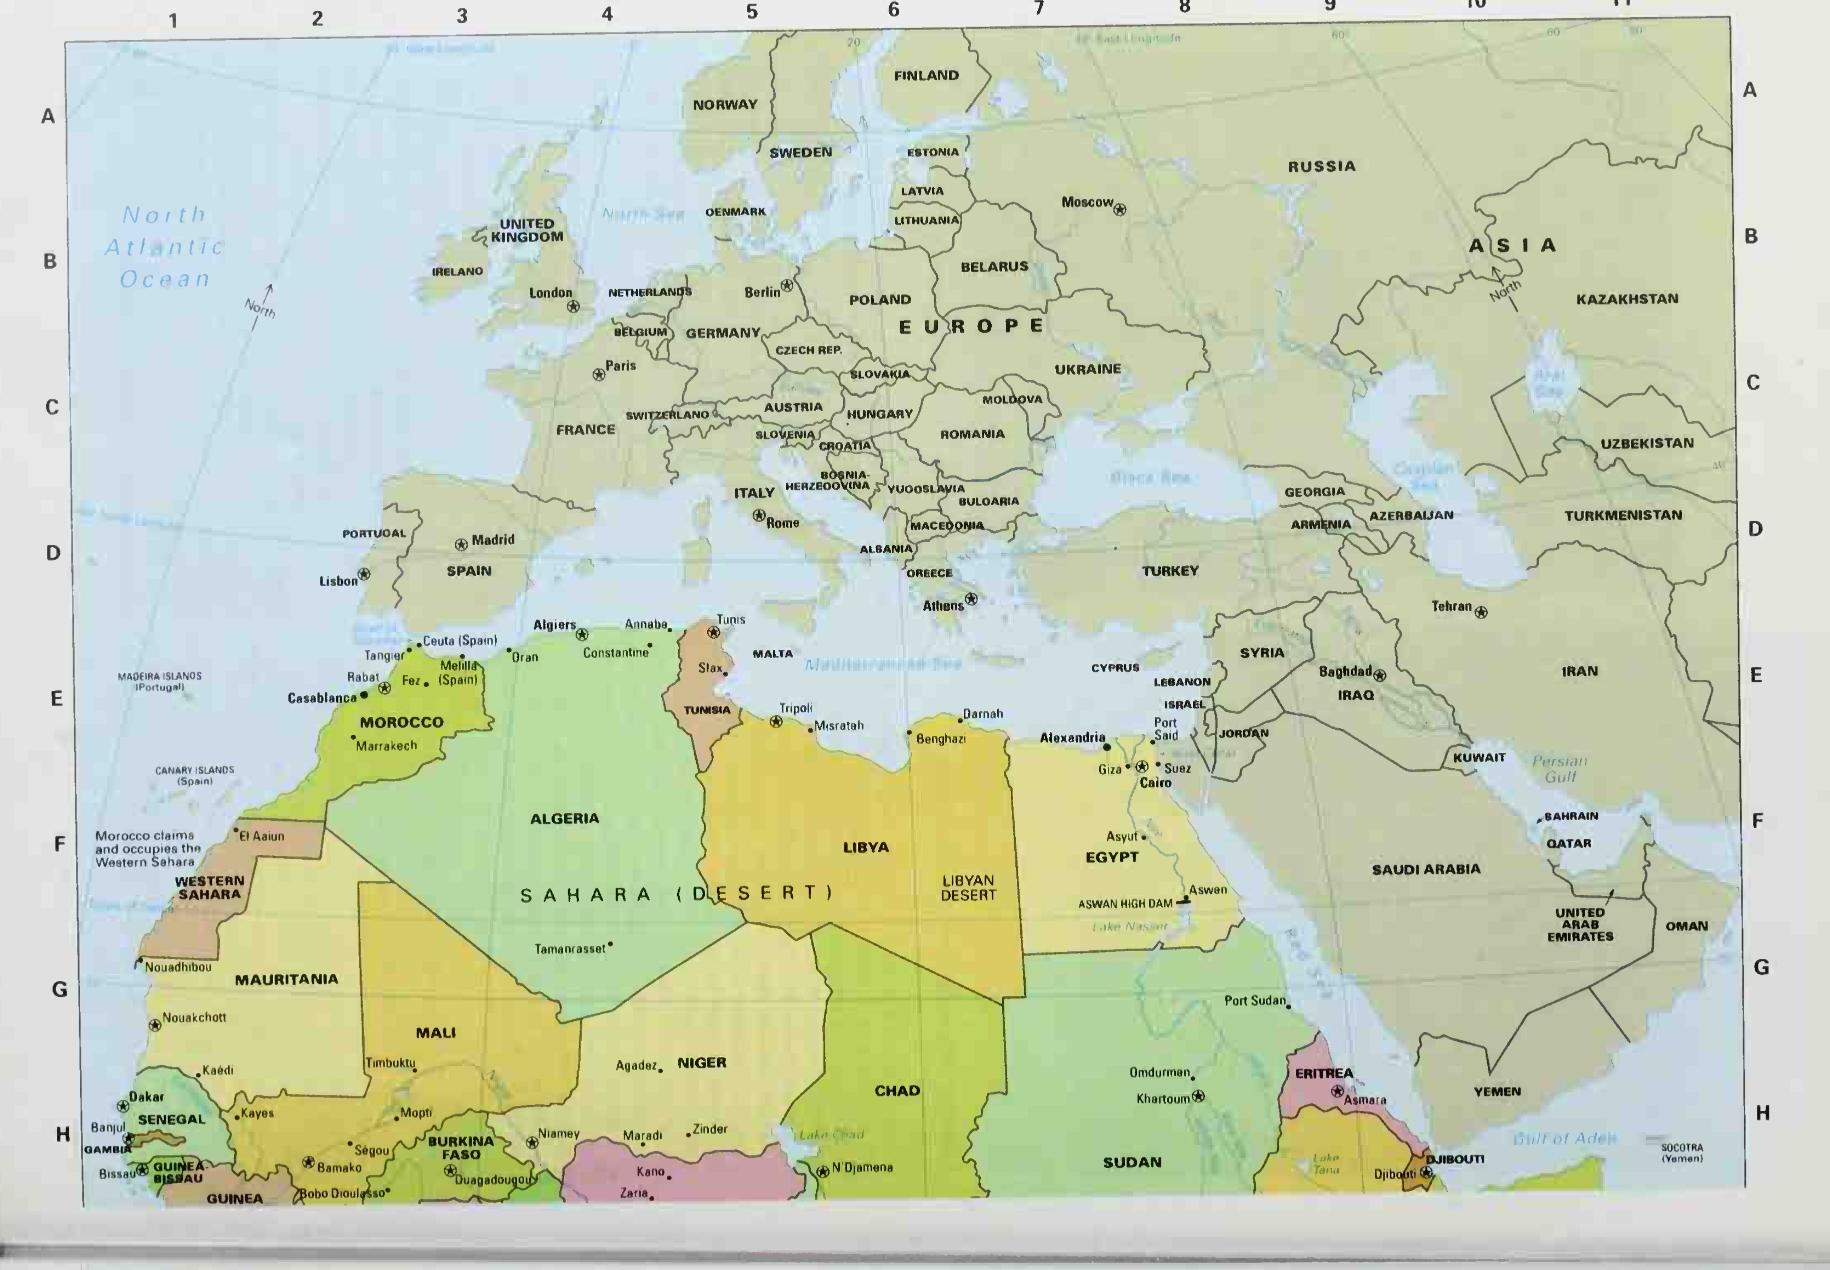
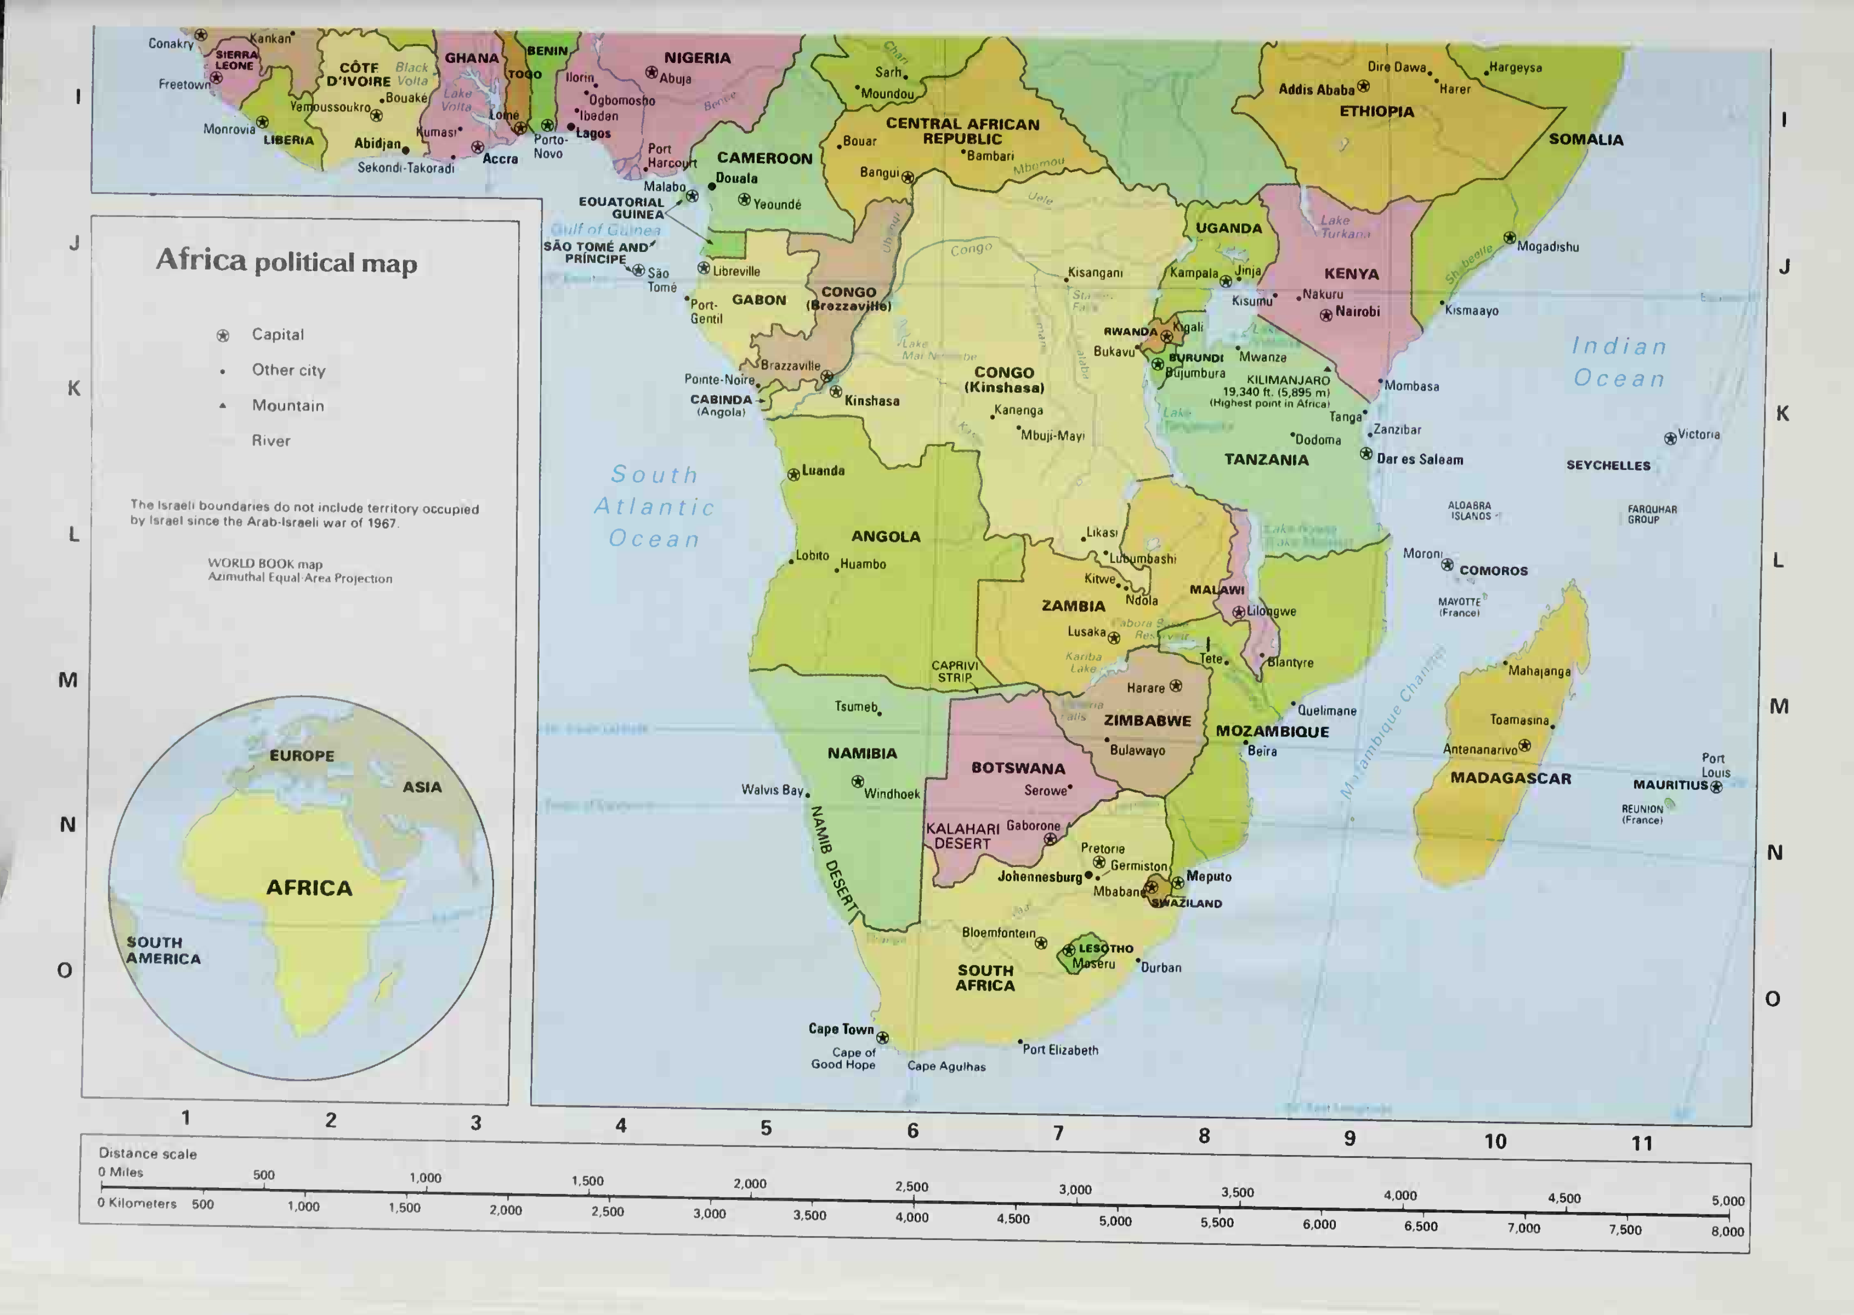
guage, religion, and way of life. The large number of ethnic groups of uneven size has helped make it difficult for many African countries to develop into unified, modern nations. In numerous cases, national boundaries cut across ethnic homelands. As a result, people may feel closer ties to neighbors in another country than to other groups in their own country. Ethnic differences have led to civil wars in several African countries.

About two-thirds of all Africans live in rural areas, where they make a living growing crops or raising livestock. In many parts of rural Africa, the people live much as their ancestors did hundreds of years ago. Since the mid-1900's, however, millions of rural Africans have flocked to the cities, where traditional life styles are being replaced by more modern ways.



Africa has great mineral wealth, including huge deposits of copper, diamonds, gold, and petroleum. It also has valuable forests. In addition, many African rivers and waterfalls could be used to produce hydroelectric power. Africa produces most of the world's cassava, cocoa beans, and yams. But Africa has the least developed economy of any continent except Antarctica.

Agriculture is the leading economic activity in Africa, but most farmers use outdated tools and methods to farm thin, poor soil. The development of manufacturing has been handicapped by a lack of money to build factories, a shortage of skilled workers, and competition from industries on other continents. Many African countries depend on only one or two farm or mineral products for more than half their export earnings. In case of crop failures or drops in world market prices, a country's economy suffers. The majority of African nations rely heavily on aid from countries outside the continent.



One of the world's first great civilizations—ancient Egypt—arose along the banks of the Nile River more than 5,000 years ago. Later, other powerful and culturally advanced kingdoms and empires developed in Africa. Even so, for many years some non-Africans called Africa the "Dark Continent." They used this name because they knew little about Africa's interior geography, and they mistakenly believed that the people of the interior had not developed any important cultures.

During the late 1400's and 1500's, Europeans began to establish trading posts in Africa. Gold and slaves became two of the continent's most valuable exports. By the late 1800's, the Europeans competed fiercely for control of Africa's resources. By the early 1900's, they had carved almost all of Africa into colonial empires.

Many Africans resisted colonial rule from the beginning. But the demands for independence did not become a powerful mass movement until the mid-1900's. Between 1950 and 1980, 47 African colonies gained independence. But leaders in many of the new nations could not handle the social and economic problems that remained after independence. Military officers overthrew the governments of many nations. In a few countries, military dictatorships emerged. In most other countries, a single political party became the ruling power. Today, ethnic rivalries and territorial disputes among nations continue to threaten the stability of Africa. Such problems as overpopulation, poverty, famine, and disease remain challenges for African leaders.

†Not shown on map. Located in the Atlantic Ocean, about 400 miles (640 kilometers) west of Dakar, Senegal.
‡Ethiopia has been independent for about 2,000 years.
§Date of union between Tanganyika and Zanzibar.
#Not shown on map. Located southwest of Africa in South Atlantic Ocean.
**Claimed by Morocco and by the Polisario Front.
Populations are 2002 estimates for independent countries and 2002 and earlier estimates for dependencies based on figures from official government and United Nations sources.

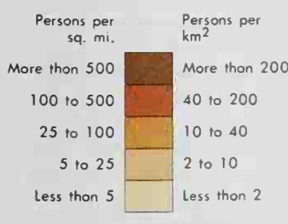
Population. Africa has a population of about 830 million. Over 600 million people live south of the Sahara. About two-thirds of all Africans live in rural villages. The rest live in cities and towns.

If all the people of Africa were evenly distributed throughout the continent, there would be only 71 people per square mile (28 per square kilometer). But Africa's population is far from evenly distributed. Large areas of the Sahara and other desert regions have no people at all. Some dry grasslands and tropical forests are also very thinly settled. On the other hand, certain areas are greatly overcrowded. The Nile River Valley in Egypt is one of the most heavily populated regions on the earth. It has an average of about 4,000 persons per square mile (1,550 per square kilometer). Other heavily populated areas include sections of the Mediterranean coast; parts of Nigeria and the west coast; the lakes region of eastern Africa; and the southeast coast.

Africa's population is increasing rapidly, partly because of improvements in medical care for children. Another reason for the rapid increase in population is a high *birth rate*—that is, the number of births in a given year per 1,000 people. Africa's rate of 38 births per 1,000 people is higher than the world average. But Africa's *death rate*—that is, the number of deaths in a given year per 1,000 people—is also higher than the world rate. The rate in Africa is 14 deaths per 1,000 people.

The average *life expectancy*—that is, the average number of years a group of people can expect to live—is about 52 years for Africans, compared with about 77 years for Americans. However, life expectancy is much lower than the average in the poorer countries of Africa. For example, life expectancy in Zambia is 37 years, and in Mozambique, 40 years. In the more developed nations of Africa, life expectancy is higher than the average for the continent. For example, in Libya, life expectancy is about 75 years, and in Tunisia, 69 years. For more information on life expectancy in African countries, see Life expectancy (table: Life expectancy at birth for selected countries).

Several reasons account for Africa's high death rate. People in many parts of the continent suffer from malnutrition. Over the years, terrible famines have killed countless Africans, especially in the regions bordering the Sahara. In addition, poor sanitation and inadequate medical services contribute to widespread disease. The



Where the people of Africa live

Africa ranks second in population—after Asia—among the world's continents. This map shows where the people of Africa live and the location of its largest cities. Heavily populated areas are shown in darker colors.

Major urban centers

- ● More than 5 million inhabitants
- • 1 million to 5 million inhabitants
- o Less than 1 million inhabitants

most serious diseases include AIDS, malaria, schistosomiasis, tuberculosis, sleeping sickness, and yellow fever.

Peoples of Africa. The peoples of Africa have rich and varied cultures and ancestry. For example, there are more than 800 *ethnic groups* of dark-skinned Africans frequently called *blacks* or *black Africans.* Each group consists of people who have in common their history, language, religion, artistic traditions, and way of life. Blacks account for almost 75 per cent of Africa's total population. Most of them live south of the Sahara. Most of northern Africa's people are Arabs. Other important African populations include Berbers, Europeans, and Asians.

Blacks were probably the original inhabitants of the continent. There are many variations in the physical features of black Africans. However, certain groups share special characteristics. One such group is the tall, slender Nilotes of eastern Africa. Some of the Nilotes are as tall as 7 feet (210 centimeters).

Pygmies are an unusually short people with reddish-brown skin. Most adult Pygmies are from 4 feet to 4 feet 8 inches (120 to 142 centimeters) tall. About 150,000 Pygmies live in Africa, mainly in the tropical forests of the Congo River Basin in central Africa.

Khoisan peoples include the San, or Bushmen, and the Khoikhoi, or Hottentots. Both groups have yellowish-brown skin and tightly coiled black hair. The San and various Khoikhoi groups once lived throughout much of the southern and eastern parts of Africa. Today, only about 50,000 San remain in Africa. They live in the Kalahari Desert of Botswana and Namibia. The only remaining Khoikhoi are the approximately 40,000 Nama people who live in Namibia.

Arabs. Africa has about 80 million Arabs. Most of them live in Egypt, in northern Sudan, and along the Mediterranean coast. The first Arabs settled in northern Africa during the 600's.

Berbers. There are about 20 million Berbers in Africa. They live mainly in Algeria and Morocco. The Berbers have lived in the northwestern part of Africa since prehistoric times.

Europeans. During the 1600's, Europeans began to settle in parts of Africa. Today, the continent has over 5 million people of European ancestry. Most are of British, Dutch, or French descent. The majority live along the Mediterranean coast, in the Republic of South Africa, and in Zimbabwe.

Asians. About a million people of Asian ancestry live in southern and eastern Africa. Most of them are descendants of people who came to Africa from India during the 1800's. About $2\frac{1}{2}$ million people of Asian ancestry also live in Madagascar, an island country southeast of the African mainland. Their ancestors began to migrate to Madagascar from Indonesia about 2,000 years ago.

Languages. Most African ethnic groups have their own language. In some cases, members of different groups speak the same language. But in most instances, language helps identify Africans as members of a particular ethnic group. More than 800 languages are spoken in Africa. As a result, communication among Africans is difficult at times. But certain languages, such as Arabic, Swahili, and Hausa, are widely spoken. In addition, millions of Africans speak more than one language, which they use when traveling or conducting business and government affairs. The languages spoken in Africa can be classified into three broad groups: (1) black African languages, (2) Afro-Asian languages, and (3) Indo-European languages.

Black African languages are spoken by about 290 million people, mainly those who live south of the Sahara and west of southern Sudan. The languages can be

grouped into three major families: (1) Niger-Kordofanian, (2) Nilo-Saharan, and (3) Khoisan.

The Niger-Kordofanian family is by far the largest of the black African language families. It includes about 300 Bantu languages spoken in central, eastern, and southern Africa. The term *Bantu* refers to both the various languages and the groups who speak them. Swahili (also called Kiswahili) is the most widely spoken Bantu language. Among other important Bantu languages are Ganda (Luganda), Kikuyu (Kikikuyu), Kongo (Kikongo), Rundi (Kirundi), Sesotho, and Zulu (IsiZulu). The Niger-Kordofanian family also includes many non-Bantu languages that are spoken mainly in western Africa. These languages include Akan; Igbo, or Ibo; and Yoruba.

Nilo-Saharan languages are used by about 35 million people who live in parts of Chad, Kenya, Mali, Niger, Sudan, Tanzania, and Uganda. Major languages in this family include Dinka, Kanuri, Maasai, and Nuer.

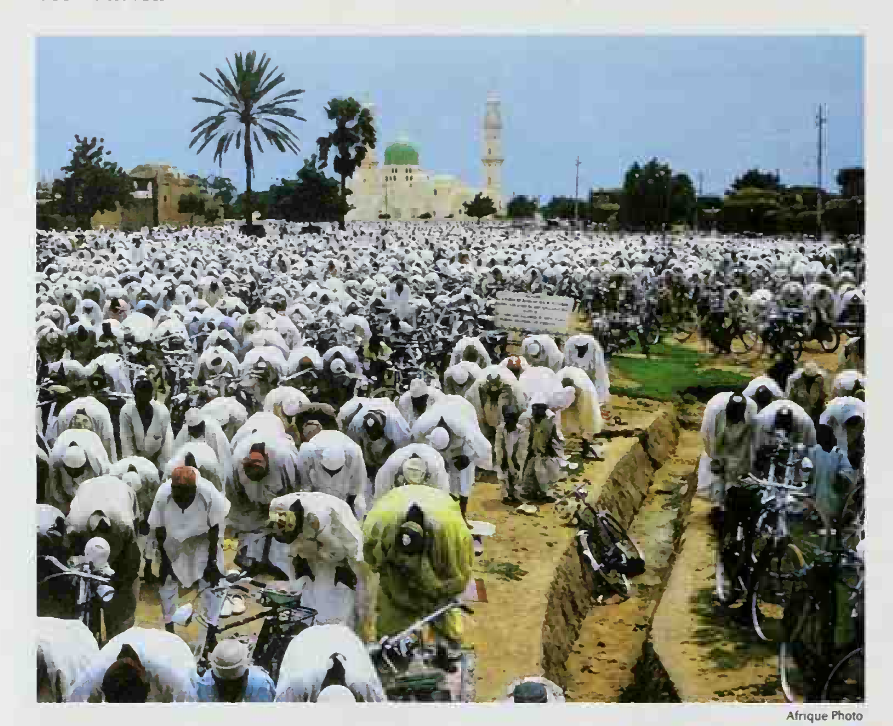
About 100,000 people, including the San and Khoikhoi of southwestern Africa, speak Khoisan languages. Two small groups in Tanzania also speak these languages. Khoisan languages are sometimes called *click languages* because many words are expressed with unusual click sounds. The languages are unrelated to any other African language.

Afro-Asian languages are spoken throughout the northern half of Africa. The Afro-Asian language family includes Arabic and Berber, the two major languages of northernmost Africa. About 100 million Africans speak Arabic, and nearly 20 million speak Berber. Other Afro-Asian languages include Amharic, Orominga or Oromo, Hausa, and Somali.

Indo-European languages. Two Indo-European languages—Afrikaans and English—are widely spoken in southern Africa. About 3 million people speak Afrikaans, a language developed by early Dutch settlers, and nearly 3 million speak English.

WORLD BOOK map

The major languages spoken in Africa are shown by labels on this map. The colors on the map indicate the language families to which the languages belong.



Sarah Errington Porlock, Alan Hutchison Library

A Nigerian ethnic group conducts a native religious ceremony, *shown here.* Each ethnic group in Africa has its own traditional religious beliefs and practices.

A large number of educated Africans speak English, French, or Portuguese in addition to their local language. The use of these European languages remains as a reflection of colonial rule in many African nations. English, French, or Portuguese serves as the official language in many countries and helps unify the people. European languages are also important for communication in international business and government affairs.

Other languages. The people of Madagascar speak Malagasy, a language of the Malayo-Polynesian family. The people of Asian descent who live in southern and eastern Africa speak various Indian languages. Most of them also know English.

Religions. Nearly 200 million Africans practice local traditional religions. There are hundreds of local religions in Africa because each ethnic group has its own set of beliefs and practices. In general, however, local religions have many features in common. They explain how the universe was created and teach what is right

Islam is one of the leading religions in Africa. Most people in the north practice Islam. But the religion is also practiced by many other Africans, such as these Nigerians praying to Allah, *left.*

and wrong. They define relationships between human beings and nature and between the young and the old. They give the reasons for human suffering and instruct people in how to live a good life and in how to avoid or lessen misfortune.

All African religions recognize the existence of a supreme god. However, most of the African religions emphasize that people should seek help by appealing to lesser gods or to the spirits of dead ancestors. People pray or offer sacrifices to the gods or the spirits to gain such things as good health or fertile land. Many religions conduct ceremonies to celebrate a person's passage from childhood to adulthood.

The more complex African religions include those of certain peoples of western Africa, such as the Dogon of Mali, the Yoruba of Nigeria, and the Ashanti of Ghana. The religions of these peoples include elaborate sets of beliefs about a supreme being and many lesser gods. Women as well as men hold important religious positions in western Africa. For additional information on traditional African religions, see Mythology (African mythology).

Nearly 150 million Africans are Muslims. Their religion, Islam, is the state religion in the countries of northern Africa. Islam is also a strong force in many neighboring nations. In addition, large Muslim minorities have great influence in such countries as Nigeria and Tanzania.

About 130 million Africans are Christians. Most of them belong to the Roman Catholic Church or to various Protestant churches. The Ethiopian Orthodox Church is the largest church of Ethiopia. In Egypt, a few million people belong to the Coptic Orthodox Church. A number of Africans belong to independent African churches that combine Christian beliefs with traditional African practices.

H. K. Brushe, Artstreet

Nomadic herding and village farming are traditional ways of life in northern Africa. In the Sahara, *left*, nomads called *Bedouins* travel between regular grazing areas with their camels, goats, and sheep. In the Nile Valley, *right*, farmers work irrigated fields using age-old methods.

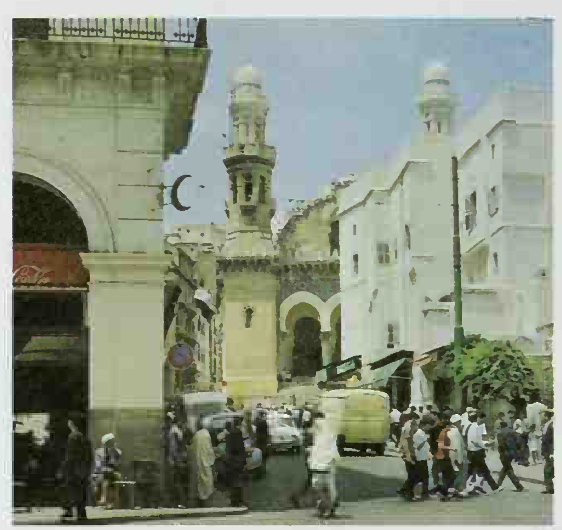
The six countries of northern Africa—Mauritania, Morocco, Algeria, Tunisia, Libya, and Egypt—have many things in common. A large majority of the people speak the same language—Arabic; practice the same religion—Islam; and share the same history—that of the Arab people. Many of the cultural features of the region extend into parts of neighboring countries to the south. But in general, the six northern nations form a distinct region that differs from the rest of Africa south of the Sahara.

Northern Africa lies along the Mediterranean Sea, and so the region has been in close contact with Europe and the Middle East throughout most of its history. France once controlled Algeria, Mauritania, Morocco, and Tunisia; Italy controlled Libya; and Great Britain ruled Egypt. However, the Middle East has shaped much of northern Africa's history, and the region is an important part of the present-day Arab world.

Brent Jones

A rural village in Morocco has houses with flat roofs and thick adobe walls. Many houses in northern Africa have thick walls to help keep out the region's intense heat.

In addition to the Arab Muslim majority, northern Africa has minority groups that differ in language or religion. For example, the Berbers of Algeria, Morocco, and Mauritania share the Islamic religion, but many maintain their own culture and speak various Berber dialects. Black Africans form another important minority group. Many of them speak Arabic as their native language and practice Islam. An important religious minority group is the Copts. They are Christians but speak Arabic and follow many Arab ways of life.



The following discussion deals chiefly with the ways of life among the Arab Muslim majority in northern Africa. For more information, see the separate articles on the countries that make up the region.

Rural life. About half the people of northern Africa live in rural areas. Most of them raise livestock or grow crops on small rented or family-owned farms. They do much of the work by hand. In some areas, farmers work on government-owned land and use machinery and modern techniques. Thousands of rural people have no land to work.

In many rural parts of northern Africa, the people live in flat-roofed houses with thick adobe walls that help keep out the region's intense heat. In highland areas, some houses are made of stucco or stone. Most rural homes are simply furnished and lack such modern conveniences as telephones and running water.

Small groups of nomads called *Bedouins* tend camels, goats, and sheep in the Sahara. Most of northern Africa was once populated chiefly by Bedouins, and Arab folklore is full of stories of their adventures. Today, less than 10 per cent of northern Africa's people are Bedouins. The Bedouins travel between regular summer and winter grazing areas and live in tents woven of animal hair.

The way of life in rural areas of northern Africa follows traditional patterns. Husbands are the providers, and wives raise the children and take care of the household. Children work on the farm or in the home. When

Anne Bolt

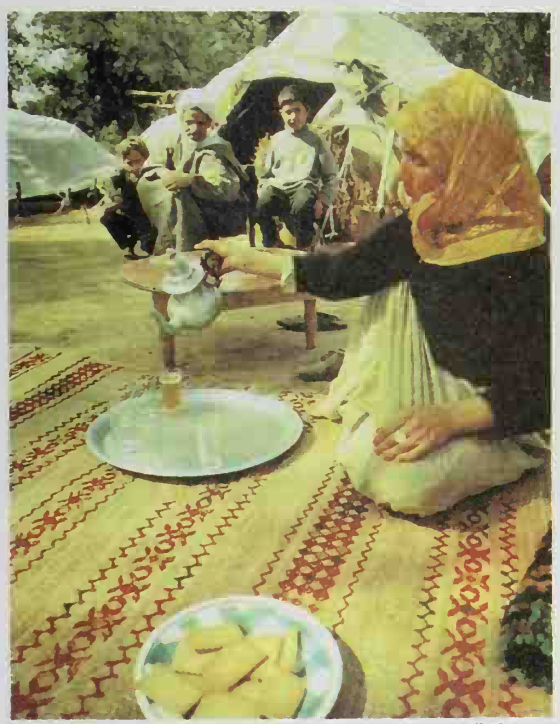
A city square in Algiers, Algeria, is lined with small shops and residences. The large building in the background with the twin towers is a *mosque* (Islamic house of worship).

parents grow old, the children are expected to look after them. The concerns and interests of most rural people are limited to their families and villages. For many of them, a weekly trip to the village market place is their only experience outside the home and farm.

City life. Cairo, the capital of Egypt, is the largest city in all Africa. It has about 6 million people. Other cities of northern Africa with more than a million people are Alexandria, Egypt; Casablanca, Morocco; Giza, Egypt, and Algiers, Algeria.

The architecture of most cities in the north reflects European and Islamic styles. Many *mosques* (Islamic houses of worship) and *souks* (outdoor markets) are typical features of the large cities. In older neighborhoods, houses and shops are crowded along narrow, winding streets. Broad boulevards, parks, and modern apartment and office buildings occupy newer sections.

In many ways, city dwellers in northern Africa have a higher standard of living than rural people. Such conveniences as automobiles, electricity, running water, and telephones are more widespread in the cities. The cities offer better medical facilities and schools, and most city workers earn more than rural people.



The attractions of city life have led more and more rural people to move to the cities. Many move in with relatives or live in slum housing. Numerous cities are overcrowded and often suffer breakdowns in the electrical, telephone, and water supply systems.

Marriage and the family. At one time, Islamic traditions governed marriage practices throughout northern Africa. These traditions included *polygyny*—the right of a man to have more than one wife. They also required a bride's family to give a *dowry* of household goods or money to the bridegroom. In addition, parents usually selected a husband or wife for each of their children. Today, polygyny remains legal in every northern country except Tunisia, but few men practice it. Dowries and marriages arranged by parents are less common than in the past, especially among city dwellers.

Edward S Ross

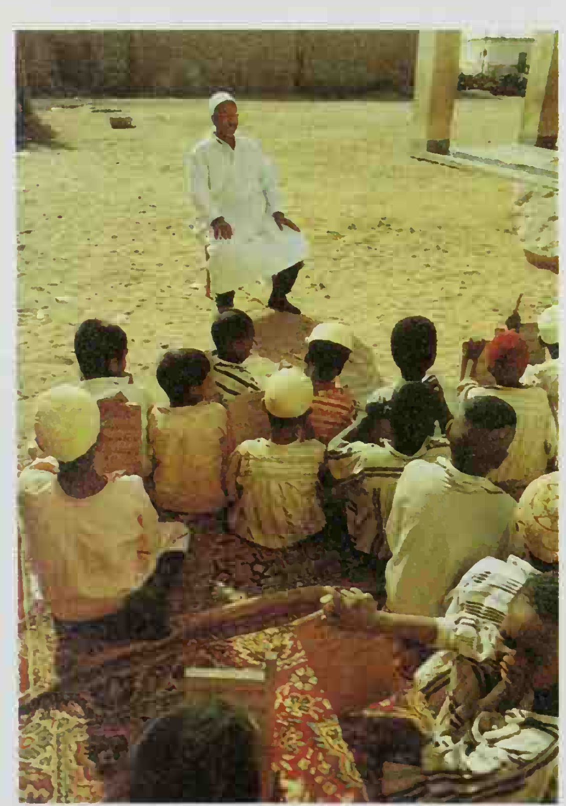
An Islamic wedding procession in Egypt leads the bride to the home of the groom. The bride, hidden from view in a tentlike covering, is riding the camel. Elaborate processions like this one are chiefly a rural tradition of the Islamic wedding ceremony.

Woodfin Camp, Inc.

A Berber shepherd family in Morocco ends their meal with mint tea and pastries made of honey, fruit, and nuts. Mint tea is served after meals and offered as refreshment to visitors.

In much of rural northern Africa, the typical household consists not only of parents and children but also of grandparents, aunts, uncles, and cousins. These *extended families* provide security, financial help, and social life. In the cities, the *nuclear family,* which consists only of parents and their children, is more common.

The traditional role of women in northern Africa has been to remain at home to care for their families. Most women in the region still follow this tradition. However, a growing number have taken advantage of educational and career opportunities that were not available in the past and now work outside the home.



Food and clothing. Flat breads and other products made from grain are the basic foods in northern Africa. *Couscous* is a common dish in much of the region. It consists of coarse grains of wheat that are steamed and served with a spicy stew, consisting of vegetables and pieces of meat in a souplike sauce. The people also eat fruits and vegetables. Meat costs too much to be part of the daily diet of most people. But occasionally, they enjoy chicken, goat, or lamb.

Many rural people in northern Africa and some city dwellers dress in traditional clothing. The men wear long, loose robes or shirtlike garments. Many men also wear a turban or skullcap. The women wear long, simple dresses, sometimes with baggy trousers underneath. Many women wear a dark cloak or shawl in public. Some follow the Islamic tradition of covering the face with a veil. Others consider the veil out of place in modern times and do not wear it. Most men and women in the cities dress in Western-style clothing.

Education. Traditionally, only religious scholars received more than an elementary school education in northern Africa. During the colonial period, European settlers established schools, but they chiefly served children of the well-to-do. Partly for these reasons, only about a third of the people can read and write. The *literacy rate* (the percentage of people who can read and write) is much lower in rural areas than in the cities.

The national governments in northern Africa are trying to improve education by building more schools and offering schooling to a greater number of people, especially in rural areas. However, several major problems obstruct progress. The population is growing faster than new schools can be built, and the costs of education are constantly increasing. Many areas have a shortage of qualified teachers. Numerous students must drop out of school to work and help support their families. In some places, families must pay for their children's education, which many families cannot afford to do.

In general, the countries of northern Africa have had more success expanding education at the secondary and college level than at the elementary level. More and more students who finish elementary school are going on to high school and college.

Jim Holland, Stock, Boston

Expansion of rural education has been a chief goal of governments in northern Africa. But a shortage of schools and teachers has hampered progress. The class above is in Libya.

Ways of life south of the Sahara

Alan Hutchison Library

Cattle herding is a proud tradition south of the Sahara for such groups as the Dinka, Fulani, Maasai, and Turkana. Cattle symbolize wealth for these people. Most groups use dairy products from the cattle but seldom eat meat. The people move with their herds to seasonal pastures.

The great majority of people who live south of the Sahara are black Africans. Kingdoms, empires, and city-states ruled much of the region until the early 1900's, when European colonial powers gained control. France governed a large portion of western Africa. Portugal controlled parts of southern Africa. Britain had colonies in the west, east, and south. Today, Africans rule almost all Africa south of the Sahara. However, most schools still conduct classes in English, French, or Portuguese, and many educated Africans speak a European language. But for the most part, European influences do not affect the everyday lives of most Africans who live south of the Sahara.

In general, Africans follow their traditional ways and observe the customs of their ancestors. Most Africans live in rural areas and make a living by farming the land. Among certain groups in parts of eastern Africa, cattle herding is an old and proud tradition. For these people, cattle are a measure of a person's wealth and social position as well as a major source of food and other necessities.

An outdoor market near Abidjan, Côte d'Ivoire, features produce sold by wholesalers, cooperatives, and farm families. Markets are also centers for hearing news and socializing.

Mineral wealth has brought greater economic development to parts of southern Africa than to any other section of the continent. But much of the wealth from mineral production is held by whites, who form a powerful minority in those parts of Africa.

This section mainly describes the ways of life among black Africans south of the Sahara. For additional information, see the separate country articles.

Rural life. About 70 percent of all Africans south of the Sahara live in rural areas, chiefly in villages. Some villages have only 40 to 50 people. But others have a population of hundreds or even thousands. Whatever its size, each village is a closely knit community of people who belong to the same ethnic group. In most villages, everyone is related through either birth or marriage.

Among some ethnic groups, kings and chiefs command great respect, though they may have limited political power. In most cases, the position of king or chief is inherited and serves as a means to link villages of the same ethnic group. Among ethnic groups that are more loosely organized, village elders may handle matters of local concern.

Most villages are simply a cluster of houses, surrounded by farmland. Larger settlements may have a schoolhouse, a few shops, and perhaps such facilities as a medical dispensary or a courthouse, where local disputes can be settled and taxes collected. Most villages also have a central square. The people gather in the central square for visiting, entertainment, and ceremonies.

Rural housing varies from village to village, depending on climate, life style, and tradition. Many Africans live in houses built of sun-dried mud with roofs of

© Agence Hoa-Qui

Modern farm machinery is used on large estates south of the Sahara that produce export crops. But most African farmers work their own small plots and use simple hand tools.

straw, grass, or leaves. As villagers become wealthy, they may construct houses of concrete blocks with sheet-metal roofs. Almost all villages have several dwellings of this type. In parts of western Africa, some houses are covered with clay and decorated with sculptured designs. The houses of African Muslims may be built around a large courtyard so that the women can go about their tasks without being seen by people outside the family. This custom follows the traditions of Islam.

In many villages, the way of life has changed little over the years. Most of the people farm the land and raise some livestock. Modern methods of agriculture are used in parts of South Africa, Kenya, and Zimbabwe and in some countries of western Africa, such as Côte d'Ivoire. However, the majority of farmers who live south of the Sahara use simple hand tools as their ancestors did.

The soil is thin and poor in much of Africa. The people have thus traditionally practiced *shifting cultivation*. A farm community clears the land of trees and bushes and plants crops for several years, until the land wears out. The community then moves to a new location. The abandoned land eventually returns to grass or forest and can be farmed again. Shifting cultivation is still common in certain areas. But in some heavily populated regions, resettlement is not possible. As a result, the farmers continue to work land that becomes poorer and poorer.

Most farm families grow *food crops* for their own use. In the grasslands of eastern and southern Africa, food crops include peanuts and such grains as corn, millet, and sorghum. In wetter areas, food crops include bananas, rice, and such roots as yams and cassava.

Farmers also grow various *cash crops*, including coffee; cacao, or cocoa beans; cotton; coconuts; and fruits. The farmers sell their cash crops for money to buy such items as bicycles, canned goods, clothing, kerosene, lamps, and matches. The farmers may also use the money from their cash crops to pay taxes as well as medical expenses and school fees.

In addition to growing crops, almost all farmers raise chickens. Many keep goats and sheep. Farmers may also sell livestock or food crops for needed money.

The typical farm family has several widely scattered plots outside the village. Each plot is planted with a different crop. Families may also rent their land or farm on land that is owned by village elders and chiefs. Some farmers also work part-time on large estates or plantations that produce cash crops. Both men and women work long hours at farming to make a living.

Rural women also spend much time doing such chores as collecting firewood, grinding grain, and obtaining water. In many villages, however, the introduction of such simple machines as water pumps and small

Soccer games draw large crowds in African cities. Soccer, also called association football, is popular throughout the continent. The game above is being played in Accra, Ghana.

hand- or machine-driven flour mills has given women more time to do other things. In most villages, everyone takes part in such major tasks as clearing new land and building houses. The people work together on such tasks, while sharing food and drink and socializing.

Some African farmers—for example, those who live along the Nile River—irrigate their crops. But most farmers depend on seasonal rains. Work and other activities therefore follow a seasonal schedule. During the rainy season, farm families work long, hard days planting and tending their crops. Food may be in short supply at that time of year. In the dry season, after the crops have been harvested, food is more plentiful. The people also have more leisure time. They spend the extra hours repairing tools and houses, visiting with friends and relatives, and trading their crops for other goods. In western Africa, women have traditionally controlled trade activities. Some women have become wealthy as a result of their trading skill. In other areas of Africa, trade matters are handled either by men or women.

Community ceremonies, which are often held in the village square, are an important part of rural African life. They mark such occasions as the first rains of the growing season, the planting of crops, and harvesttime. Some groups have annual ceremonies in which secret societies of elders dance to rid the community of evil forces and witches. Entire communities, as well as people from neighboring villages, may gather for ceremonies related to births, marriages, funerals, the curing of the sick, and the passage of children into adulthood. These community gatherings strengthen family ties and religious beliefs.

In many parts of rural Africa, young men leave their villages and work at least a few years as migrant laborers. They travel to cities and towns in hope of earning enough money to get married, to set up a small business, or to go to school. In parts of central and southern Africa, many men get temporary jobs as miners. The women left behind in the villages must do much of the farm work themselves.

Nomadic herding is a way of life for people in parts of Africa, particularly in dry areas near the Sahara and in the highland regions of eastern Africa. Such nomadic peoples as the Dinka, the Fulani, the Maasai, the Toubou, the Tuareg, and the Turkana follow well-established routes to find grazing land for their herds of cattle, sheep, goats, or in some cases camels.

The nomadic herders depend mainly on their livestock for food. The men and boys tend the herds, and the women care for the household. Some nomadic groups, such as the Maasai of eastern Africa, build huge corrals for their livestock. Within the corrals, the people construct igloo-shaped houses of brush, mud, and dried manure. Other nomads live in tents made of animal skins or hair.

City life. City dwellers make up only about 30 percent of Africa's total population south of the Sahara. But the percentage is much higher in some countries, such as Congo (Brazzaville), Djibouti, Equatorial Guinea, Mauritius, and South Africa. Throughout Africa, more and more rural people are moving to the cities to seek work. Cities south of the Sahara with populations of more than a million include Addis Ababa, Ethiopia; Cape Town, South Africa; Johannesburg, South Africa; Kinshasa, Congo (Kinshasa); and Lagos, Nigeria.

Some towns and cities south of the Sahara have existed for centuries. The Ethiopian town of Aksum may have been founded more than 2,000 years ago. When the first Europeans reached western Africa during the 1400's, such cities as Timbuktu in Mali and Ibadan and Kano in Nigeria were thriving economic and cultural centers. Europeans established many other cities in Africa, starting in 1652 with the Dutch settlement at Cape Town in what is now the Republic of South Africa.

In most cities south of the Sahara, the architecture reflects both traditional and modern styles. The newer sections of the cities have parks, hotels, tall office and apartment buildings, and large stores. Many older

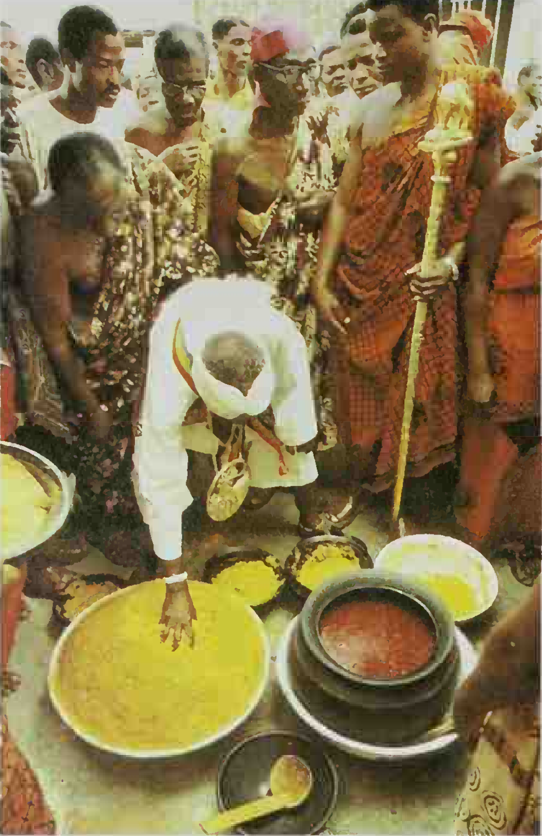
Rural housing varies according to climate, tradition, and available materials. Houses of the Ndebele of South Africa, *shown here*, are made of dried mud and colorfully painted.

neighborhoods have houses and shops crowded along narrow streets. Open-air markets, where people buy food, clothing, and a variety of other goods, are common in many cities.



Like city people in northern Africa, most city dwellers south of the Sahara have a higher standard of living than rural people. The cities provide better schools and better medical facilities than the countryside. For people with the necessary skills, the cities may offer well-paying job opportunities in government, business, industry, and other fields.

City life styles vary widely. Some people are wealthy and live in luxury apartments or large, modern houses. Most of the people, however, live in unplanned neighborhoods of small, one-story houses. Many houses are built of wood or concrete blocks and have corrugated iron roofs.

Like cities in the north, most African cities south of the Sahara face serious problems. The sharp increase in city populations has made it difficult for governments to provide enough housing and efficient public transportation. The water supply, sewerage, and electrical systems are overloaded. Many cities also have a large number of unemployed workers.

Marriage and the family. Strong feelings of loyalty and cooperation bind African families closely together. Such feelings are shared among all family members, not only parents and children but also grandparents, aunts, uncles, and cousins. The family helps its members with business concerns, employment, legal matters, and various other affairs. The family also cares for members who are sick or elderly. Most Africans still seek the advice and approval of their relatives before making any important decision.

According to traditional African beliefs, marriage is more than an agreement between a man and a woman to live together. Marriage is also a way to acquire more relatives, both by gaining in-laws and by having children. In general, the families of the bride and groom must consent to a marriage before it may take place. Among most African peoples, a man or his father or uncles must give a *bridewealth* in money, livestock, or other valuables to a woman's family before the man may marry her. Africans do not consider this traditional bridewealth as a payment for the bride but as a way to show her importance and the value they place upon the new ties with her relatives.

Women in Mali grind grain into flour, *above.* Both sexes share the farm work in Africa, but certain chores are assigned to either men or women. Food preparation is the work of women.

Most African ethnic groups permit polygyny. Many men follow this custom and so have more than one wife. The husband is expected to divide his attention and possessions equally among his various families. Each wife expects to have her own house, livestock, and other goods. Some Africans and foreign missionaries have tried to end the bridewealth and polygyny. But the traditions remain important among most ethnic groups south of the Sahara.

Africans trace their family ties in several ways. A few groups trace their ancestry through both the mother and the father. But most ethnic groups are organized as *patrilineages*—that is, relatives are linked by their descent through the male members of the family. Property is inherited only through the male side of the family, and

© Bernard Pierre Wolff, Photo Researchers

Western-style clothing is worn by many Africans in urban areas. The scene above is in Dar es Salaam, Tanzania. Some city people and most villagers, however, wear traditional clothing.

fathers have legal control over their children. *Matrilineages* are common among some groups, particularly in central Africa, Congo (Kinshasa), and the forests of western Africa. In these groups, family members are linked through the women. Property is inherited through the female side of the family, and the brothers of a mother have legal control over her children.

Each kinship system has its own names for relatives. These names classify family members into groups that differ from those commonly used in Western countries. In the United States, for example, a brother of a person's father and a brother of a person's mother are both called *uncle.* But many Africans use a different name for a brother of one's father and a brother of one's mother. In a similar manner, most Africans do not group all their cousins together under one term but refer to them by different terms according to the specific family ties involved.

Among some African peoples, families form larger groups called *clans.* All the members of a clan consider themselves to be descended from the same ancestor. Many clans observe certain rules. For example, members of the same clan may not be allowed to marry. Like the family, the clan offers protection and security for its members.

For some Africans, the strength of family ties has decreased as more and more rural people have moved to the cities. But even in the cities, relatives may live in the same neighborhood, and most city dwellers keep in close touch with relatives in the country.

Food and drink. South of the Sahara, most Africans in both the cities and the countryside eat one large meal daily, usually in the evening. They have only light snacks at other times of the day. The main meal is a time for socializing with relatives and neighbors. The men and boys generally eat separately from the women and girls. In many households, the people gather around a large bowl of food set on the ground and scoop up the food with their fingers or with pieces of bread.

The typical African meal consists of a starchy food, such as rice, flour cooked into a porridge, or yams. The food is served with a sauce containing vegetables or bits of meat. A common food in tropical areas is the *plantain,* a large kind of banana. Plantains may be fried or cooked into a porridge. They may also be dried and ground into flour.

Most African families eat meat only on special occasions. At such times, the men and the elderly receive bigger portions of meat than the women and children. The people eat chicken, goat, lamb, or beef. Fish are important in the diet of people who live along seacoasts, rivers, and lakes. Africans who keep cattle live largely on milk, cheese, and a thick sour milk product that resembles yogurt. Some of them also draw blood from their cattle, mainly for ceremonial occasions. They drink the blood raw or eat it boiled or mixed with the yogurt.

Many Africans make beer from honey or from such grains as maize and millet. They also make wine from the sap of certain kinds of palm trees.

In some parts of Africa, the people suffer from malnutrition because of periodic food shortages or the lack of a balanced diet. Long droughts, particularly in regions

Traditional clothing styles in Africa often feature bright colors and bold patterns. Elaborate costumes and jewelry may be worn for special occasions. At the left, a village chief arrives at an Islamic festival in Chad. He and his attendants wear long, flowing robes and turbans.

near the Sahara, sometimes lead to terrible famines and thousands of people may die of starvation.

Clothing. Clothing styles vary throughout Africa south of the Sahara according to climate and custom. City dwellers often wear Western-style clothes. But other city people and most villagers prefer to wear African clothing, which often features bright colors and bold patterns.

In western Africa and regions near the Sahara, many men wear a long flowing robe or baggy trousers and a loose shirt or tunic. A small cap or turban is also customary among many African men. Many African women take a length of cloth and wrap it around themselves into a dress. They may also wrap a cloth around the head in the style of a turban or scarf. Some Muslim women follow Islamic tradition and cover the face with a veil when they go out in public. Many rural men and women tie a piece of fabric around the waist or at the shoulder to form a cloak. Some African herders wear simple garments made of leather. Rural people generally go barefoot or wear sandals. Colorful necklaces, bracelets, anklets, and earrings are part of the everyday clothing of some Africans. Among the Ashanti of Ghana and certain other ethnic groups, kings and their courts dress in gorgeous robes on special occasions. See **Clothing** (pictures: Traditional costumes).

Education. Hundreds of years ago, Muslim scholars established near the edges of the Sahara some of the first schools in Africa. These schools taught Islam, the Arabic language, and science. But for most Africans, education did not involve going to school. Parents taught their children what they needed to know to get along in society and to make a living. Some young people, especially in areas of western Africa, served as apprentices in craft associations, where they were trained in such skills as metalworking, woodcarving, pottery making, or weaving.

Christian missionaries taught some Africans south of the Sahara how to read and write as early as the 1500's. But large advances in education did not begin until the 1900's, when the European colonial powers decided they needed more Africans to fill jobs in government and industry. Britain, France, and other colonial powers established schools in Africa.

Today, many African governments south of the Sahara strive to build schools and to extend education to as many people as possible. A greater number of Africans than ever are attending elementary school and going on to high school and college.

In spite of the progress in education, serious problems remain. Most African adults who live south of the Sahara cannot read and write. However, the literacy rate varies greatly from country to country. In Gabon and Zimbabwe, for example, the literacy rate is higher than 60 percent, and in Tanzania, about 90 percent. But in such countries as Benin, Burkina Faso, and Mali, the literacy rate is only about 20 percent. In many places, especially rural areas, there is a shortage of schools, educational materials, and qualified teachers. A large number of children do not attend school at all, and many others leave after only a few years to help their families earn a living.

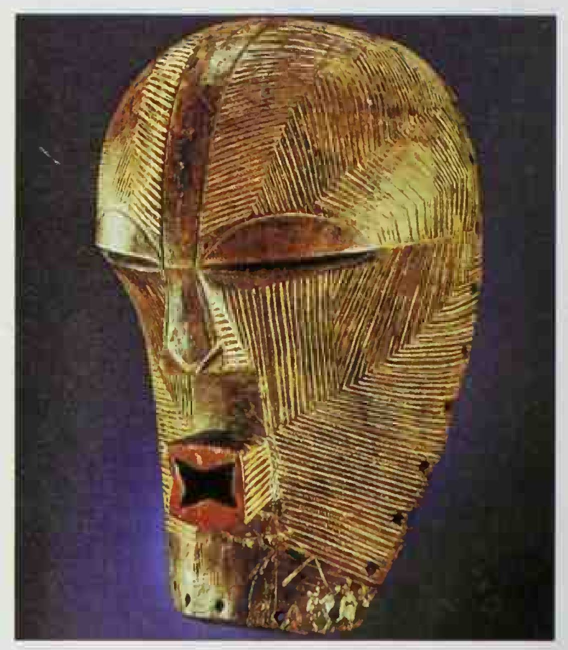
College education is available in most African countries. Before the 1940's, most Africans had to go abroad to get a college education. These students attend Dakar University in Senegal.

Various arts have been highly developed in parts of Africa for thousands of years. The oldest known African artworks are prehistoric paintings that have been found in Namibia, in the Sahara, and in other areas on rocks and on the walls of caves and rock shelters. The architecture, painting, and sculpture of ancient Egypt are world famous. Today, many African peoples create fine examples of beadwork, basketry, pottery, leatherwork, metalwork, weaving, and textile dyeing. Excellent craftwork can be seen in tools and household items as well as in decorative ornaments and ceremonial objects.

The art of northern Africa differs from that of the rest of the continent. In the north, artists create beautiful works in a distinct style called *Islamic art.* Outstanding examples of this style are the many magnificent mosques located throughout northern Africa. The artists of northern Africa are also known for their superb textiles, metalwork, glassware, and other craftwork.

Sculpture. African sculpture includes figures, masks, decorated boxes, and other objects for religious, ceremonial, and everyday use. Many early African sculptures were made of wood. Because wood is perishable, few of these works remain. Some excellent examples of early African sculpture are made of brass, ivory, and a kind of earthenware called *terra-cotta.* The oldest known African sculptures from south of the Sahara are terra-cotta figures created about 500 B.C. by the Nok culture of central and northern Nigeria. Superb brass and terra-cotta heads were made in what is now Ife, Nigeria, especially from about the 1100's to the 1400's. Artists in the former kingdom of Benin, in western Africa, made high-quality ivory ornaments as well as brass figures, heads, and plaques from the 1400's to about the 1700's.



Few people outside Africa knew about African sculpture until the 1900's. But it became a major influence on Western art. The imaginative designs and simple, dramatic forms of African sculpture influenced such famous artists as Georges Braque of France, Henry Moore of Britain, and Pablo Picasso of Spain.

Today, African sculptors work in wood or various metals and follow the traditional styles of their ethnic group. Ethnic groups known for their sculpture include the Yoruba of Nigeria; the Dogon and Bambara of Mali; the Senufo, Baule, and Dan of Côte d'Ivoire; the Fang of

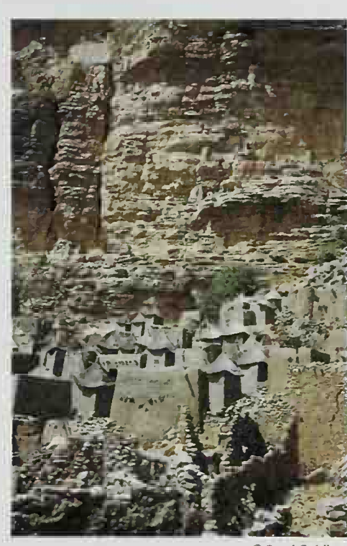
Gabon; and the Kongo, Kuba, Luba, and Lega of Congo (Kinshasa). For additional information, see **Sculpture** (African sculpture).

Music. African music has a wide range of styles. In northern Africa, music follows Arab traditions. Arab religious chants and the use of various northern instruments have also spread southward and influenced the music of peoples in parts of Chad, Ghana, Mali, Niger, Nigeria, Senegal, and Sudan. Ethiopian music developed from ancient Coptic music. Traditional black African music includes choral singing, music performed for entertainment at royal courts, and songs and dances for religious events. Black African musicians use a variety of drums as well as such instruments as harps, horns, flutes, pipes, lyres, zithers, and xylophones.



The complicated rhythms, responsive choral singing, and flattened, or *blue,* notes found in black American work songs and church music reflect African traditions. African music has also influenced Western popular music and jazz, West Indian calypso, and Latin American dance music. See **Music** (African music).

Literature. Africa has a rich tradition of oral literature, which has been passed from one generation to another. The literature includes histories of ethnic and kinship groups, legends of cultural heroes, stories of tricksters, animal fables, proverbs, riddles, and songs of praise for chiefs and kings. Oral literature has a role in religious ceremonies and serves to record the past, to teach morals and traditions to young people, and to glorify political leaders. It is often recited to music before family groups or larger audiences. Today, scholars are recording African oral literature to preserve it.

In the past, only a few areas of Africa had a written literature. Scholars in the north produced works in Arabic or in Swahili and Hausa using Arabic script. A small educated minority in Ethiopia wrote in Coptic script. Since the 1900's, African writers have produced works in various African languages, including Hausa, Somali, Swahili, Yoruba, and Zulu. But most present-day written literature is in English, French, or Portuguese, the languages of former colonial powers. African written literature today includes plays, novels, and poetry.

Africa covers approximately 11,657,000 square miles (30,190,000 square kilometers), about a fifth of the earth's total land area. The continent is an enormous plateau, most of which is covered by deserts, forests, and grasslands.

Land regions. Africa can be divided into two major land regions: (1) Low Africa and (2) High Africa.

Low Africa consists of northern, western, and central Africa. Except for a few coastal plains and mountain ranges, most of the region lies from 500 to 2,000 feet (150 to 610 meters) above sea level. Low Africa can be subdivided into six smaller land regions. They are (1) the Coastal Lowlands, (2) the Northern Highlands, (3) the Saharan Plateau, (4) the Western Plateau, (5) the Nile Basin, and (6) the Congo Basin.

The Coastal Lowlands form a narrow border along most of northern Africa and the bulge of western Africa. The area has fertile farmland, forests, sandy beaches, deserts, and swamps.

The Northern Highlands are a mountainous region that stretches across parts of Algeria, Morocco, and Tunisia. The Atlas Mountains in this region have deposits of phosphate rock, iron ore, and manganese.

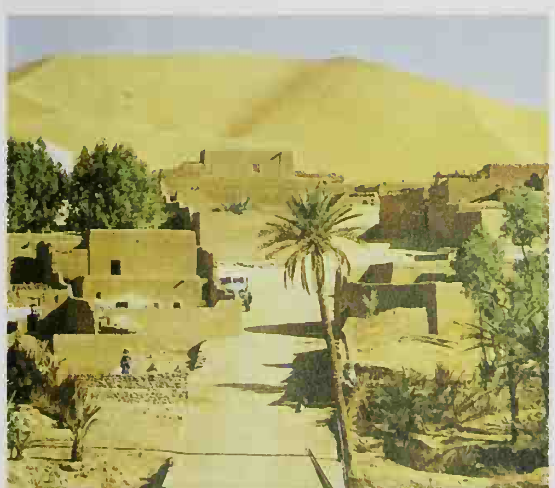
The Saharan Plateau covers most of northern Africa. The Sahara, in turn, occupies most of the plateau. Isolated clusters of mountains rise up from the plateau in places. Valuable deposits of petroleum and other minerals lie beneath the Sahara. The desert merges with a dry grassland called the Sahel at the southern boundary of the Saharan Plateau.

The Western Plateau lies south of the Saharan Plateau. It consists of forests and grasslands. The Niger and other rivers flow through the region.

The Nile Basin is a flat, dry region that borders the Nile River and its tributaries in northeastern Africa. In addition to fertile farmland along the Nile, the region has deserts in the north and a huge swamp called the Sudd in the south.

The Congo Basin, in west-central Africa, includes most of the land drained by the Congo River and its tributaries. Tropical rain forests cover much of the Congo Basin.

High Africa consists of eastern and southern Africa. Most of the region is more than 3,000 feet (910 meters) above sea level. High Africa can be subdivided into five smaller land regions. They are (1) the Rift System, (2) the Eastern Highlands, (3) the Southern Plateau, (4) the Coastal Lowlands, and (5) Madagascar.



The Rift System extends from Eritrea to Mozambique. The region consists of the Great Rift Valley, which is a series of parallel cracks in the earth that form deep, steep-sided valleys. Lakes and mountains add to the region's beauty. The region also has some of Africa's best farmland because of its rich volcanic soil.

The Eastern Highlands are grassy plains that provide grazing land for livestock and many kinds of wild animals. The Rift System cuts through the Eastern Highlands.

The Southern Plateau covers most of southern Africa. Much of it is flat or rolling grassland used for crops and pasture. The region also has deserts, swamps, and forests. Rugged mountains and cliffs rim the plateau in the south and west. Deposits of diamonds and gold lie in the Southern Plateau.

The Coastal Lowlands border the high plateaus of eastern and southern Africa. The lowlands include productive farmland, sandy beaches, and swamplands.

Madagascar, the world's fourth largest island, lies about 240 miles (390 kilometers) southeast of the mainland in the Indian Ocean. Although the island is part of High Africa, it can be divided into two chief land regions. The *Coastal Lowlands* form a narrow band along the east coast and broaden to a wide fertile plain on the west. The *Central Highlands,* which run almost the full length of the island, have some peaks over 9,000 feet (2,700 meters) above sea level.

Norman Meyers, Bruce Coleman Ltd.

Africa's spectacular sights include Victoria Falls, *left*, and Kilimanjaro, *right*, a towering dormant volcano. Victoria Falls is on the Zambezi River, between Zambia and Zimbabwe. Kilimanjaro rises 19,331 feet (5,892 meters) in Tanzania. It is Africa's highest point.

Deserts, grasslands, and forests. Deserts cover about two-fifths of Africa. The Sahara, the world's largest desert, stretches across northern Africa from the Atlantic Ocean to the Red Sea. It covers about 3 $\frac{1}{2}$ million square miles (9 million square kilometers). The Sahara is a region of bare rock, boulders, gravel, and sand dunes, broken only by a few oases and the fertile Nile Valley. The Namib Desert borders the Atlantic coast of southwestern Africa. The Kalahari Desert lies inland from the Namib.

Grasslands called *savannas* occupy more than two-fifths of Africa. They form a broad curve that extends from the Atlantic coast just south of the Sahara, across eastern Africa, and back westward to the Atlantic south of the Congo Basin. Tall grasses, thorny bushes, and scattered trees grow in this area. Thicker woodlands cover areas with more rainfall. But closer to the deserts, there are fewer trees and shorter grasses.

Forests cover less than a fifth of Africa. Many people outside the continent think that much of Africa is a jungle, which must be hacked through with an ax or knife. But true jungle is rare in Africa. Most of the forests are tropical rain forests. These forests, with their many kinds of broadleaf evergreen trees, grow in the Congo Basin and in parts of western Africa and Madagascar. The floors of the forests tend to be fairly open and clear. Pockets of dense and tangled mangrove swamps fringe some coastal areas in the west and east and in Madagascar. Other forests grow in the highlands of eastern Africa, in the mountains of the northwest, and in parts of the south.

Rivers and waterfalls. The Nile River, the world's longest river, flows 4,160 miles (6,695 kilometers) northward from east-central Africa to the Mediterranean Sea. Most of Africa's other major rivers, including the Congo and the Niger, empty into the Atlantic. Rivers that flow into the Indian Ocean include the Limpopo and the Zambezi.

Rapids and waterfalls make navigation difficult on many African rivers. But they provide the continent with about 15 percent of the world's potential water power. Hydroelectric power projects have been built on a number of rivers. Some projects also provide irrigation water and flood control. Several waterfalls, including spectacular Victoria Falls on the Zambezi, are popular tourist attractions.

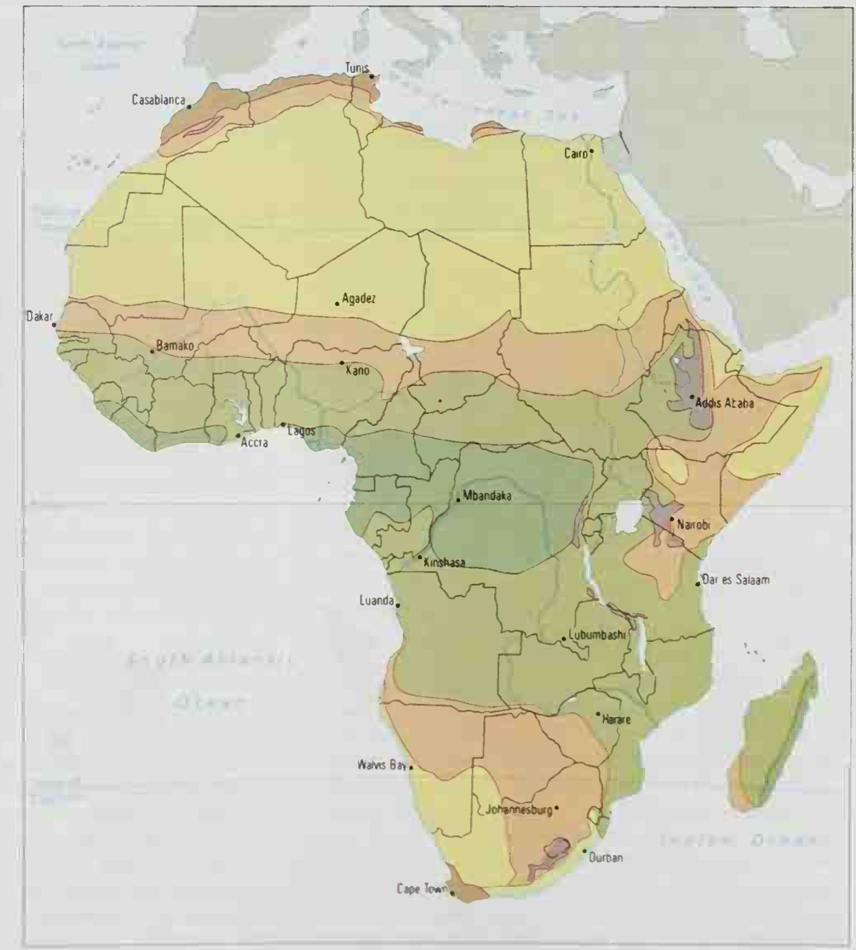
Lakes. Most of Africa's large lakes lie in the east, where chains of long, deep lakes have formed in the bottoms of the rift valleys. One of these lakes, Tanganyika, is the longest freshwater lake in the world. It is 420 miles (680 kilometers) long and more than 4,700 feet (1,430 meters) deep. Other large rift lakes include Nyasa, Albert, and Turkana. Africa's largest lake, Victoria, lies in a shallow basin between two chains of rift valleys. It covers 26,828 square miles (69,484 square kilometers) and is second in size only to Lake Superior among the world's freshwater lakes.

Mountains. Volcanic activity created most of Africa's highest mountains. The two tallest peaks—19,331-foot (5,892-meter) Kilimanjaro and 17,058-foot (5,199-meter) Mount Kenya—were formed in this way. Although they rise near the equator in eastern Africa, both mountains have glaciers and are covered with snow much of the year. Volcanic activity also produced the Ethiopian Highlands; the isolated Tibesti Massif in the Sahara; and Mount Cameroon, the highest peak in western Africa. Volcanic rock covers the Drakensberg, a mountainous region where the plateau of southeastern Africa drops sharply to the sea.

Two major nonvolcanic mountain ranges of Africa are the Ruwenzori Range and the Atlas Mountains. The Ruwenzori Range rises on the border of Uganda and Congo (Kinshasa). The Atlas Mountains extend from Morocco to Tunisia and form Africa's longest mountain chain. The Atlas Mountains are part of the same mountain system as the European Alps.

Most of Africa has a warm or hot climate, but the humidity and amount of rainfall vary dramatically from area to area. The map below illustrates Africa's climate patterns. The maps on the next page indicate the average January and July temperatures and the average yearly *precipitation* (rain, melted snow, and other forms of moisture).

Africa has the largest tropical area of any continent. The equator runs through the middle of Africa, and about 90 per cent of the continent lies within the tropics. In countries south of the equator, the seasons are opposite those of countries that lie north of the equator. But temperatures are high the year around almost everywhere in Africa. The variations between summer and winter temperatures are slight. In fact, the difference between daytime and nighttime temperatures in most parts of the continent is greater than the difference in the average temperatures between the coldest and warmest months. For this reason, some people say that nighttime is the "winter" of the tropics.



Africa's highest temperatures occur in the Sahara and in parts of Somalia. The highest temperature ever recorded in the world was 136° F. (58° C) in the shade at Al Aziziyah, Libya, on Sept. 13, 1922. At I-n-Salah, Algeria, and along the north coast of Somalia, July temperatures soar to 115° F. (46° C) or higher almost every day. Nighttime temperatures, however, may drop sharply. The Sahara also has the greatest seasonal range of temperatures in Africa. Winter temperatures in the Sahara average from 50° to 60° F. (10° to 16° C). Near the equator, temperatures may average 75° F. (24° C) or more the year around. But temperatures of more than 100° F. (38° C) are rare.

The coolest regions in Africa are the northwest, the highland areas of the east, and parts of the south. In Johannesburg, South Africa, for example, the average temperature in January, the warmest month, is 68° F. (20° C). Frost and snowfall are common in the mountains of Africa.

Rainfall is distributed very unevenly in Africa. Most areas receive either too much rain or too little. In parts of the west coast, for example, annual rainfall averages more than 100 inches (250 centimeters). In Monrovia, Liberia, an average of more than 40 inches (100 centimeters) of rain falls during the month of June alone. In contrast, more than half of Africa receives less than 20

What Africa's climate is like

Much of Africa has a tropical or desert climate. The map and legend show what the climate is like throughout the continent.

Tropical Wet: Always hot, always wet. Heavy precipitation well distributed throughout the year.

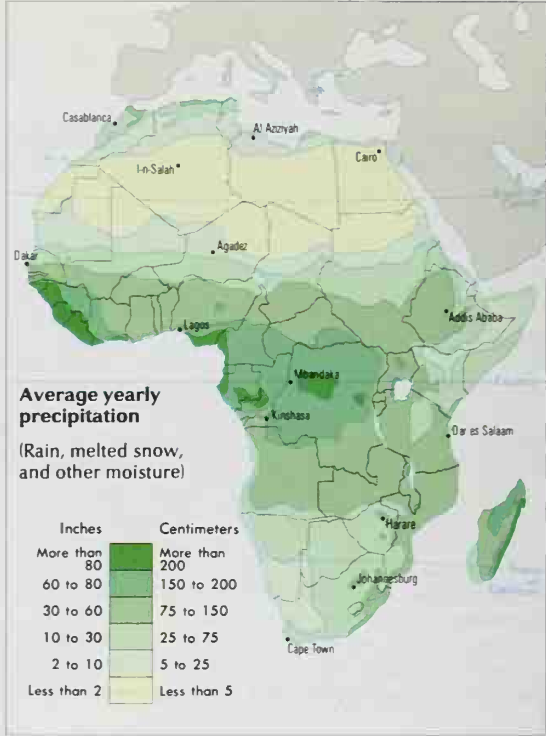
Tropical Wet and Dry: Always hot. Both wet and dry seasons. Heavy precipitation in wet season.

Semiarid: Hot to cold. Great changes in daily temperature except near coast. Light precipitation.

Desert: Hot to cool. Great changes in daily temperature except near coast. Very little precipitation.

Subtropical Dry Summer: Hot, dry summers and mild winters. Moderate precipitation in winter.

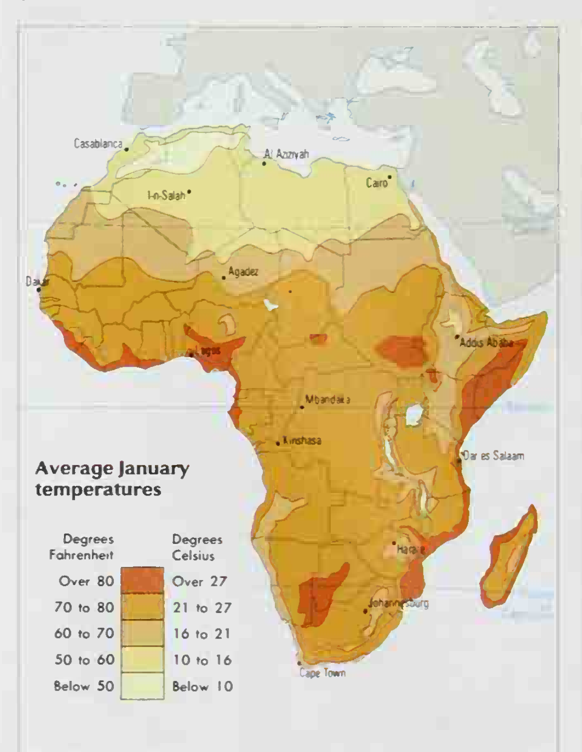
Subtropical Moist: Warm to hot summers and mild winters. Moderate precipitation in all seasons.



Highland: Because of altitude, highlands are generally cooler and wetter than adjacent areas.

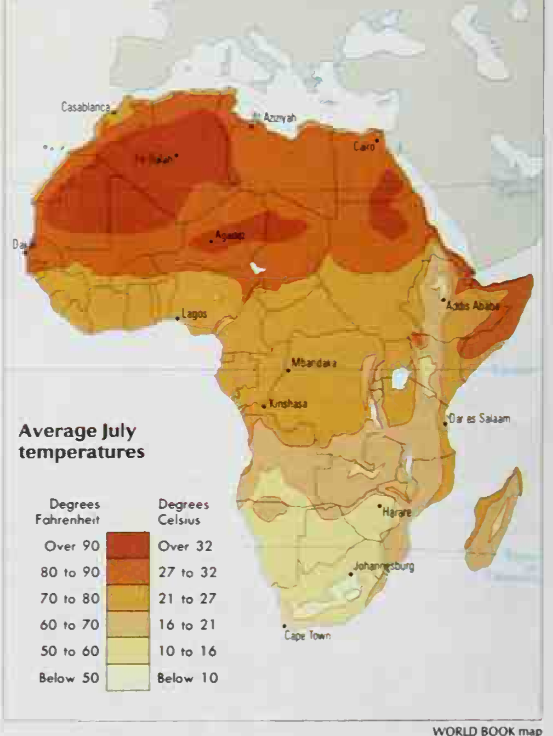
WORLD BOOK map

inches (50 centimeters) of rainfall yearly. The Sahara and the Namib Desert receive an average of less than 10 inches (25 centimeters) a year. In parts of the deserts, rain may not fall for six or seven years in a row. Then when it does rain, many children are startled because they have never seen rain before.



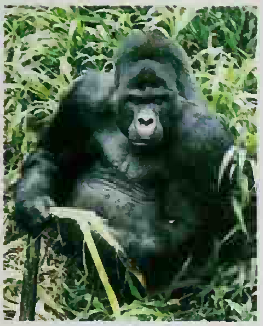
Rain falls the year around in the forests of the Congo Basin and the coastal regions of western Africa. But almost all the rest of Africa has one or two seasons of heavy rainfall separated by dry periods. In some regions of Africa, the amount of rainfall varies sharply from year to year rather than from season to season. Since the late 1960's, droughts have caused much suffering in Africa. Millions of Africans have died of starvation and related causes. The hardest-hit areas include Ethiopia and the Sahel region on the southern edge of the Sahara.

Africa's climate has made agricultural improvement difficult. In areas with limited and unreliable rainfall, farmers may be uncertain of what crops to plant. Some farmers grow a number of crops with different moisture needs in the hope of having at least one successful harvest. Other farmers may grow only one or two kinds of crops and risk starvation if not enough rain falls. In areas with too much rainfall, heavy downpours wash away nourishing substances in the soil. The hot, humid climate in much of Africa encourages the spread of insects that destroy livestock and cause various diseases in people.



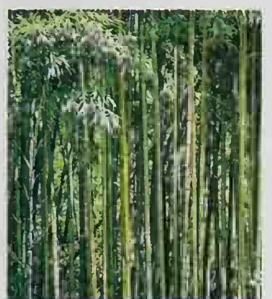
WORLD BOOK map

Rainfall is unevenly distributed in Africa. Equatorial regions receive 60 inches (150 centimeters) or more annually. The Sahara receives less than 2 inches (5 centimeters).



WORLD BOOK map

WORLD BOOK map



Temperatures are high all year throughout most of Africa. The maps above show the average January and July temperatures across the continent. January is a winter month in the north and a summer month in the south. But in July, the north has summer, and the south has winter.

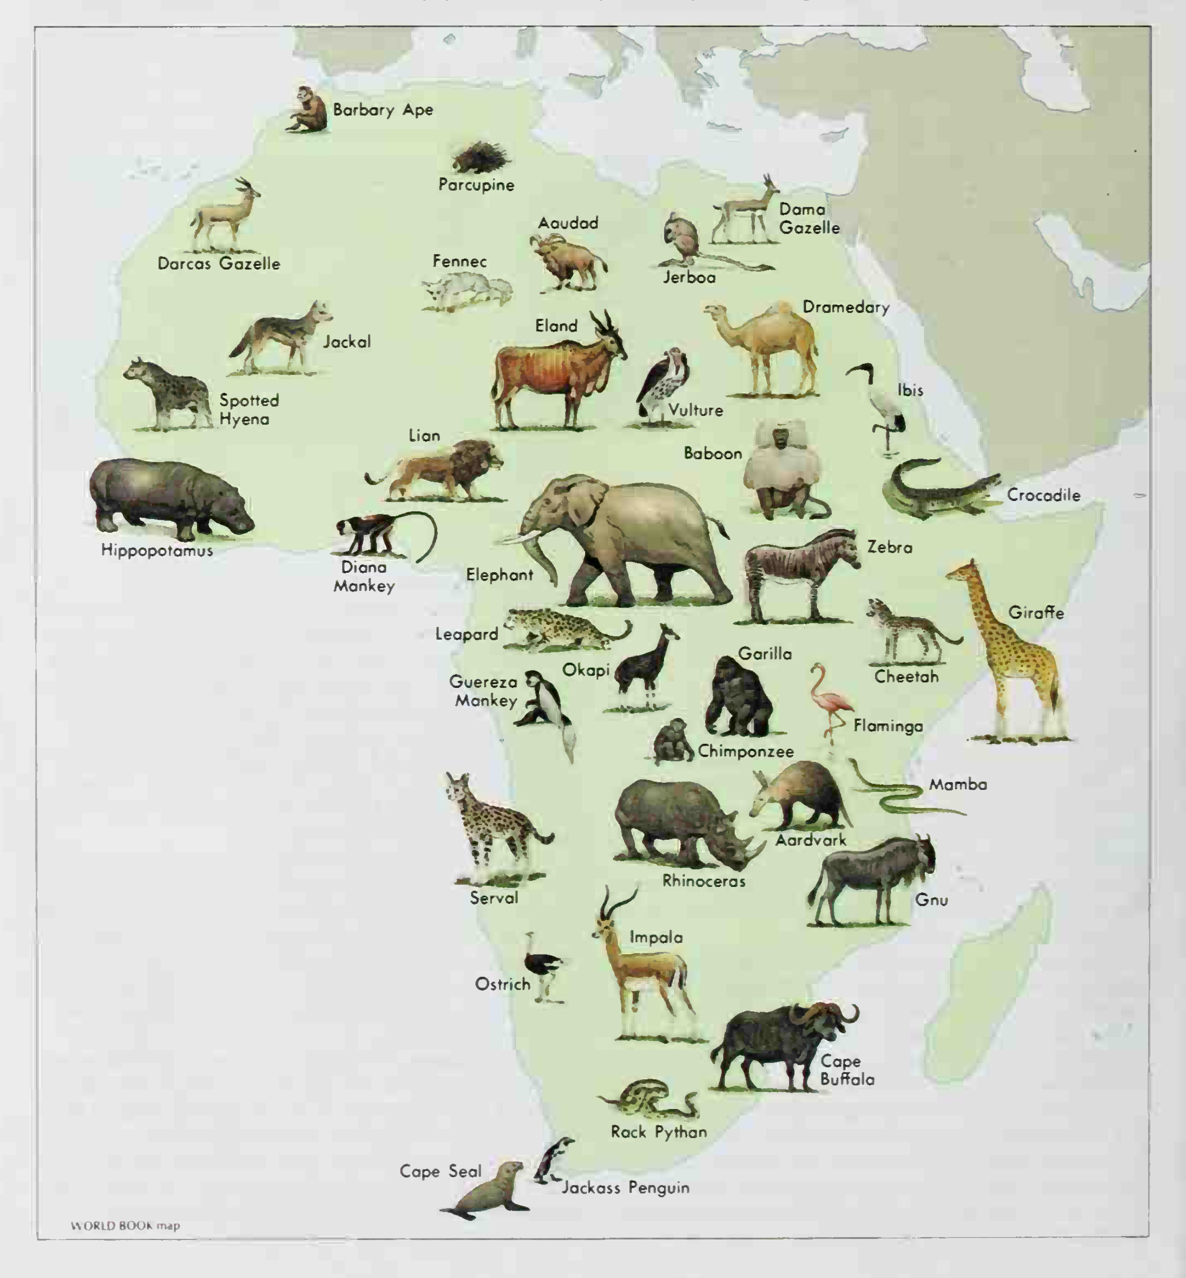
African plant life varies according to climate. For example, bamboo grows in tropical forests, the baobab tree in savannas, and the Welwitschia in southwestern desert areas.

Native animals. Africa's wild animals are world famous. The continent has thousands of species of mammals, reptiles, amphibians, fishes, birds, and insects. In the east and south, huge herds of antelope, buffaloes, giraffes, and zebras roam the grasslands. They are preyed on by such animals as cheetahs, hyenas, jackals, leopards, and lions. A few remaining large herds of elephants live in the east and the southeast. Baboons are common in many parts of Africa. Crocodiles and hippopotamuses live in tropical rivers and swamps, and chimpanzees and monkeys dwell in the forests. Such large water birds as flamingos, pelicans, and storks can be found in eastern and southern Africa. Ostriches live in the south and east parts of Africa and in the western Sahara. Lemurs live in Madagascar.

Africa once had many more wild animals than it has today, and they were much more widespread. Ancient paintings on rocks show that hippopotamuses and giraffes once lived in regions that are now deserts. Gradual changes in climate partly caused the reduced number and smaller range of Africa's animals. But the most important cause has been people, who have overhunted the animals and destroyed much of their natural environment to make room for farms and cities. Such animals as the black rhinoceros, the gorilla, and the elephant will eventually die out completely unless they are protected from human interference.

African countries have taken steps to save their rich wildlife heritage. The killing of certain animals is prohibited in many areas. A number of African countries have established game reserves and national parks. Hunting is forbidden in these areas, and modern methods of wildlife conservation are practiced to protect the animals. Some hunters go on carefully regulated *safaris* (hunting expeditions). Many people today go on photographic safaris to take pictures of the animals in their natural environments. However, *poaching* (illegal hunting) continues to be a problem.

Many rural Africans have opposed wildlife conservation efforts. In some areas, for example, wild animals compete with farmers and herders for scarce land. Wild animals can destroy an entire crop or threaten the lives of villagers and their farm animals. Wild animal meat is important in the diet of some Africans, and people accused of illegal hunting may actually be struggling to feed their families.



Native plants. Africa's plant life varies according to climate and altitude. The spectacular rain forests of western and central Africa have hundreds of kinds of trees. They include oil palms; fruit trees; ebony, mahogany, and other hardwood trees; and softwood okoumé trees, which are used to make furniture, plywood, and veneers. Mangrove trees stand on stiltlike roots in swampy areas along tropical coasts. Olive and oak trees

and such evergreen bushes as myrtle grow in the northwestern parts of Africa and at the southern tip of the continent.

Plants that withstand drought and fire cover the grasslands. In addition to various grasses, grassland plants include thick-trunked baobab trees, acacia trees, and thorny euphorbia bushes. *Steppes,* the very dry grasslands near the deserts, have shorter grasses and fewer varieties of other plants. In the desert oases and *wadis* (dry riverbeds), there are date palms, doum palms, tamarisks, and some kinds of acacias. Certain kinds of grasses and shrubs may appear briefly in the deserts after a rare rain.

In the mountainous highlands of Africa, bamboo thickets, podocarpus trees, tree ferns, and cedar trees grow on the lower slopes. On the upper slopes, meadows are covered with grasses, buttercups, and violets. Mosses and lichens grow near the mountaintops.

Animals of Africa This map shows some of the mammals, birds, and reptiles of Africa. Wild animals were once much more numerous and widespread there than today. Hunting and expanding settlement have greatly reduced the animal population and have put some species in danger of extinction.

People have destroyed much of Africa's natural plant life. Farmers have cleared forests for cropland. Hunters have burned grasslands to drive out game animals. The overgrazing of livestock has turned some steppes almost into deserts.

Introduced species. Numerous plants and animals that are common in Africa were introduced from other parts of the world by traders and colonists. They brought many of Africa's most important food crops. These food crops include bananas, cassava, and corn, as well as such cash crops as cocoa beans and tea. Eucalyptus trees, which originated in Australia, now grow in many parts of Africa and are widely used for firewood and building construction. European settlers introduced most African farm animals. Such animals include cattle, goats, and sheep. Camels, which provide food and other necessities in much of northern Africa, originated in Asia.

Plants of Africa Some of Africa's trees, shrubs, and other plants are pictured on this map. Much of Africa has a tropical climate. However, the land regions of the continent vary dramatically, ranging from deserts to tropical rain forests. As a result, Africa has a wide variety of plant life.

The Republic of South Africa is the only African nation generally classified as economically developed. All other African countries have a developing economy. These countries have an especially low *gross national product* (GNP). GNP is the value of all goods and services produced in a country yearly. A country's *per capita* (per person) GNP is determined by dividing the GNP by the population. Among most African countries, the per capita GNP is less than $400, compared with about $21,900 in the United States.

Agriculture employs more workers and contributes more to the total value of production in Africa than does any other economic activity. Africa leads the world in the production of cacao, or cocoa beans; cassava; cashews; cloves; palm kernels; vanilla beans; and yams. It is also a major producer of bananas, coffee, cotton, peanuts, rubber, sugar, and tea. Africans raise more than two-thirds of the world's camels, nearly a third of its goats, and about a seventh of its cattle and sheep.

For their own use, African farmers grow a variety of food crops. In the wet tropical areas of western and central Africa, the chief food crops include bananas, plantains, rice, and such roots as yams and cassava. In

WORLD BOOK map

the grasslands of the east and south, farmers grow corn, millet, and sorghum. In northern Africa, farmers raise barley and wheat and use irrigation to grow fruits and vegetables. Farmers in the oases of the Sahara grow dates and small crops of barley and wheat.

About three-fifths of Africa's cultivated land is used mainly for *subsistence agriculture*—that is, for growing food crops for a farmer's own use. However, subsistence agriculture has been decreasing as more and more African farmers produce only cash crops, which are grown mainly for export. In addition, most subsistence farmers use at least some of their land to raise cash crops. The shift from subsistence agriculture to the growing of cash crops is causing problems. For example, food shortages occur in some areas because fewer farmers are growing food crops. In addition, some former farmers have moved to cities to find work. Another problem is that farmers who grow only cash crops cannot depend on a steady income because of frequent changes in prices on the world market.

In the past, almost all African farmland was owned cooperatively by members of the various ethnic groups. Today, individual land ownership is widespread. But the cooperative tradition remains strong. Many farmers combine their lands, buy equipment and seed as a group, and join cooperatives to sell their crops.

In northern Africa, many farmers rent their land. Africa also has numerous large estates and plantations that produce such cash crops as coconuts, palm products, rubber, sisal, sugar, and tea. Thousands of laborers work full time or part time on these farms.

Overall, agricultural productivity in Africa is low for several reasons. Most African farmers work small plots and use inefficient methods. Most of Africa's soil is thin and poor. Heavy rains in parts of western and central Africa wash away precious topsoil. In some areas, periodic droughts, floods, or insect invasions destroy crops or sharply reduce crop yields. Cattle cannot be raised in many parts of Africa because of the unfavorable climate and tropical diseases. In addition, the types of cattle that can be raised in Africa produce less meat and milk than cattle in North America and Europe.

Petroleum production is important in several African countries. Algeria, Libya, and Nigeria are the leading producers. These men are drilling for oil in Nigeria.

Mining accounts for more than half the total value of Africa's exports, but it employs fewer than $1\frac{1}{2}$ million workers. Africa's mineral wealth is unevenly distributed. Five countries—South Africa, Libya, Nigeria, Algeria, and Zambia—produce about four-fifths of all the minerals Africa exports. The government controls the mining industry in several African nations and uses the income to help finance various government projects.

South Africa is the world's largest producer of gold. Libya and Nigeria both rank among the leading produc-

Industrial development has been a chief goal of most African countries since winning independence from European colonial powers. This automobile assembly plant is in Nairobi, Kenya.

ers of petroleum in the world. In addition, Algeria is an important oil producer. Africa also produces about three-fourths of the world's cobalt and platinum, more than two-fifths of its vanadium, and about a third of its chromite. In addition, Africa is a leading source of copper, diamonds, phosphates, and uranium. Other important mineral products of Africa include antimony, iron ore, manganese, natural gas, and tin.

Manufacturing has a small role in Africa's economy. In the past, colonial rulers emphasized agricultural and mineral production to obtain raw materials for industries in their home countries. Today, therefore, even new nations with abundant raw materials have few major industries. Many African countries cannot afford to build costly factories and have a shortage of skilled workers, managers, and technicians. In addition, competition from American and European industries has discouraged major industrial growth in Africa.

Since the mid-1900's, large cities and towns in most of Africa have developed small industries that produce such consumer goods as beer, cigarettes, furniture, shoes, soap, and soft drinks. Some African factories also make such products as automobile parts and textiles.

South Africa is the most highly industrialized country in Africa. It produces nearly two-fifths of the continent's manufactured goods. South Africa's factories turn out a wide range of products, including automobiles, chemicals, clothing, processed foods, and iron and steel. The next most important industrial countries of Africa are Egypt, Algeria, Morocco, and Nigeria.

Forestry and fishing. Africa has about a fourth of the world's forests. However, less than 15 percent of the forests are used to provide timber and other products. The most valuable trees include such hardwoods as African walnut and mahogany and such softwoods as eucalyptus and okoumé. The forest industry is especially important in Cameroon, Congo (Brazzaville), Congo (Kinshasa), Côte d'Ivoire, Gabon, Ghana, and Nigeria.

Fishing fleets along Africa's seacoasts bring in large quantities of anchovies, mackerel, sardines, tuna, and other fishes. Africa exports much of this catch in the form of fish oil and fish meal. Rivers and lakes provide plentiful freshwater fish, which are important in the protein-poor diet of many Africans. Major freshwater fishing grounds include the lakes of eastern Africa and the swamps around Lake Chad and the upper Nile River.

Mining and manufacturing in Africa

This map shows the location of Africa's chief mineral resources and manufacturing centers. Major mineral-producing areas are shown in large type, and lesser ones in small type. Manufacturing centers are in red.

Transportation. Africa has more than 800,000 miles (1,300,000 kilometers) of roads, but only about 60,000 miles (97,000 kilometers) are paved. In many areas, roads become impassable during the rainy seasons. Less than 2 per cent of all Africans own an automobile, and almost all these people live in cities. In much of Africa, buses and trucks follow regular routes to transport people and goods between villages and towns. Many people simply walk or ride a bicycle. In many parts of the continent, donkeys or other animals are used to carry goods and people. Camels are the most reliable means of transportation in the Sahara.

Africa has about 59,000 miles (95,000 kilometers) of railroad track. South Africa has the continent's best railway system, and a good network of track links parts of northern Africa. In other areas, the rail lines are mainly single-track routes used to carry minerals and farm products to seaports that handle foreign trade. Most of Africa's railroads were built in colonial times.

The African coasts have few good natural harbors, but engineers have built harbors with modern shipping facilities in almost every coastal country. Inland waterways serve as transportation routes in relatively few parts of Africa. Rapids and waterfalls block navigation on many rivers. In addition, rivers and lakes in areas of limited seasonal rainfall often become too shallow to travel on for part of the year. In tropical rain forests, many villagers use dugouts or other small craft for transportation on the rivers. Railroads and roads link navigable sections of the Congo, Niger, and Nile rivers with ocean ports.

Most African countries have their own airline, which provides domestic and international service. The major African cities are also served by foreign airlines.

Communication. The cities of Africa have far better communication services than the rural areas. Newspapers and magazines from Europe and the United States are available in most large cities, and cities throughout Africa also publish local newspapers. Most African countries provide television service. But there is an average of only about 1 television set for every 25 people in Africa. Few rural people ever see TV. Radio is the chief means of mass communication. Radio stations broadcast in every African country. Africa has about 1 radio for every 5 people. Even in remote areas, there is at least one radio in most villages. Villagers often gather before the radio to listen to news programs and other broadcasts.

Telephone service in Africa is limited mainly to the cities and larger towns. The continent has about 7 million telephones, compared with about 180 million in the United States. South Africa has more than half of all the telephones in Africa. In most African countries, telephone service was originally installed by colonial rulers to assist in colonial administration. As a result, even today telephone service between Africa and Europe is often better than between or within African countries.

International trade. Africa accounts for only about 4 per cent of the total value of imports and exports in international trade. But trade plays a major role in the continent's economy. About a fourth of Africa's total production is exported. Foreign trade has influenced the development of transportation and communication systems, the location and expansion of cities, and the growth of cash crop agriculture.

Africa trades chiefly with Europe, Japan, and North America. Very little trade occurs between African countries. Africa's major imports include food, iron and steel, machinery, and motor vehicles.

Petroleum accounts for more than half the total value of African exports. Other leading exports include cocoa, coffee, gold, and natural gas. A number of African countries rely on only one product for most of their export income. Libya and Nigeria, for example, depend chiefly on petroleum; Botswana on diamonds; Gambia on peanuts; Ghana on cocoa; Guinea on bauxite; Uganda on coffee; and Zambia on copper.

The importance of foreign trade and the dependence on a small number of export products have made African economies highly sensitive to changes in world market prices. Rapid changes in prices make economic planning difficult. As a result, Africa has been active in international efforts to control price changes and improve trade terms. Algeria, Gabon, Libya, and Nigeria belong to the Organization of Petroleum Exporting Countries (OPEC), an association of oil-producing nations that has a great deal of influence over the world market for oil. Other African countries that depend heavily on a single product for export income are joining similar exporting organizations.

Foreign aid. Almost every African country depends to some extent on foreign aid. Such aid consists of grants of money; loans; and technical assistance in such areas as agriculture, education, and health.

Individual nations and various international organizations provide Africa with aid. France, Britain, and the United States, in that order, are the leading individual contributors. The United Nations (UN), through various affiliates, provides huge amounts of aid. Other major contributors include the World Bank and its affiliate, the International Development Association; the Economic Development Fund and other funds of the European Union; and the African Development Bank and its affiliate, the African Development Fund.

Egypt receives more foreign aid than any other country in Africa. Other African countries that receive large amounts of foreign aid include Ethiopia, Kenya, Morocco, Mozambique, Sudan, and Tanzania.

Foreign aid has helped African countries establish industries, improve agricultural productivity, and build houses, roads, and schools. Foreign aid also has provided African countries with food and supplies in times of drought and other natural disasters.

However, foreign aid has not always been wholly beneficial. Many loans call for high interest payments. As a result, several countries receiving aid are finding it extremely difficult to repay the loans. Some loans require that the country receiving aid buy materials from the donor country. In many cases, the donor countries thus end up with more financial benefits than the receiving countries. In addition, large amounts of aid sometimes are used to build impressive government structures such as dams, superhighways, or other projects that do not help most of the people.

History

Reproduction of a rock painting (3500-3000 B.C.); Musee de l'Homme, Paris (© Erich Lessing, Magnum)

Rock paintings on the walls of caves and rock shelters were made thousands of years ago by peoples who lived in Africa. This painting was found in the Tassili-n-Ajjer region of Algeria.

Africa has been called the "birthplace of the human race." The oldest evidence of humanlike creatures and people found anywhere in the world is bones and other fossils discovered at many sites in eastern and southern Africa. From this evidence, most scientists have concluded that the earliest human beings lived about 2 million years ago in eastern Africa. The crude stone tools made by these people gave the Stone Age its name. In time, the Stone Age culture spread to other continents. For detailed information on the earliest people and the Stone Age, see the article **Prehistoric people**.

This section discusses the broad outlines of African history. For the history of a particular country, see the *World Book* article on that country. See also the articles listed under "History" and "People" in the *Related articles* at the end of this article.

The coming of agriculture was a revolutionary development in early Africa. In time, it led to great economic, social, and political changes. Most Stone Age Africans had lived by hunting wild animals and by gathering such plant foods as berries, seeds, and roots. People who lived near lakes and rivers ate chiefly fish.

The hunters and gatherers lived in small groups. As the seasons changed, the groups could thus move easily from place to place to follow the migrations of animals and to search for plant foods. But after people learned how to grow crops and how to tame and raise animals, they no longer had to move about to get food. They could then establish permanent settlements.

The spread of agriculture in Africa occurred over thousands of years. No one knows for certain when or where it began on the continent. In parts of Africa, agriculture probably was introduced by people who had migrated from other places. In some other areas, the people may have experimented with native wild grasses and eventually figured out how to grow the grasses as cultivated grains. Many experts believe that farming began in the Middle East and then spread westward into northern Africa. By about 5000 B.C., people in the north knew how to tame and raise animals and how to grow such crops as barley and wheat. Some experts believe that Africans in other areas, including what are now Ethiopia and Kenya, may have developed agriculture on their own even earlier.

Scientists believe that various groups of people were living in many parts of Africa when agriculture was developing there. Light-skinned peoples lived in the north. Pygmies roamed the central forests, and yellowish-skinned Khoisan peoples lived in much of the south. Black Africans lived in the Sahara and neighboring grasslands. The Sahara was not a desert at that time. It was a grassland, where hunters tracked game, fishing communities lived on the catch from many lakes and rivers, and farmers grew grain and raised livestock.

About 4000 B.C., Africa's climate gradually became drier and drier. Many farmers of the Sahara moved southward and began to grow such crops as rice and yams. By about 1500 B.C., the Sahara had become a vast desert and a barrier to the easy movement of people between northern Africa and the rest of the continent. However, trade routes that eventually crossed the desert kept some links open for communication between the north and the south.

Early civilizations. The fertile soils of the Nile Valley supported some of the earliest and richest farming communities in Africa. In time, some of these communities developed into small states. Cities within the states served as centers of government and trade. About 3400 B.C., the small states combined into two large states—Upper Egypt and Lower Egypt. Menes, king of Upper Egypt, united the two states about 3100 B.C. This united kingdom was to become the first great African civilization and one of the greatest civilizations in history. Egypt reached the height of its power about 1400 B.C. Later, it became part of the Persian Empire and the empire of Alexander the Great. Roman armies conquered Egypt in 30 B.C. and made it a province of the Roman Empire. By that time, Rome controlled the north coast of Africa.

South of Egypt, a kingdom called Kush arose after 1000 B.C. It lasted until about A.D. 350. Kush was strongly influenced by Egypt and became a major center of art, learning, and trade.

Trade between Africans and other peoples and between Africans themselves helped spread the use of metals. The Egyptians were probably the first Africans to use bronze tools instead of stone tools. The use of bronze spread to Egypt from the Middle East about 3000 B.C. By about 1000 B.C., people in northern Africa were using iron. Kush became one of the continent's first important centers of iron mining and iron manufacturing.

Southward migrations. About the time of Christ, black peoples who spoke Bantu languages began one of the great migrations in all history. They moved southward from what is now the Nigeria-Cameroon border region into the forests of central Africa. From there, the migrations continued for more than 1,000 years. Bantu-

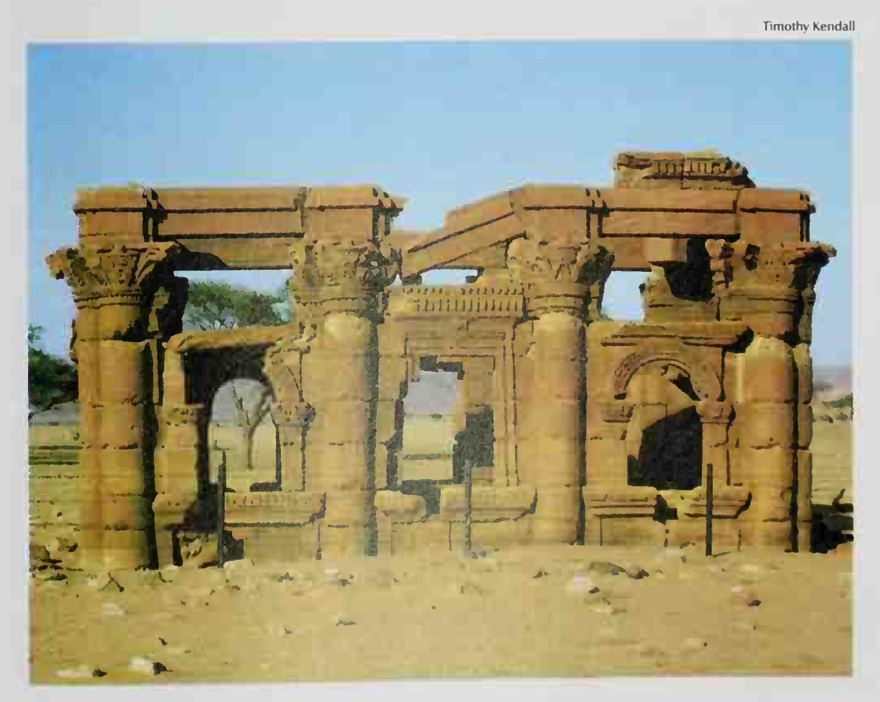
speaking peoples eventually settled throughout central, eastern, and southern Africa. Their way of life was based on farming and the use of iron tools.

Historians believe that the migrations began—and continued—because of the constant need for more land to support a growing population. The migrations had major effects on the vast region they covered. As the peoples migrated, they spread their knowledge of farming and ironworking. In time, Bantu languages became the chief language group south of the Sahara.

Historians believe the migrations were peaceful. As the Bantu-speaking peoples moved south, they met such hunting peoples as the Pygmies of the central forests and the Khoisan peoples of the east and south. Some hunters married Bantu-speakers and adopted their way of life. Others retreated into the forests or deserts of central and southern Africa.

The influence of Christianity. During the A.D. 300's, Christianity became the state religion of the Roman Empire, which included Egypt and the rest of the north coast of Africa. A Germanic tribe called the Vandals invaded the empire during the 400's. The tribe followed an outlawed Christian belief called *Arianism.* The Vandals ended Roman rule along most of the north coast. In the 500's, the area fell under orthodox Christian influence again, when it became part of the Byzantine Empire.

Two areas just south of Egypt—Aksum (or Axum) and Nubia—were strongly influenced by the Roman Empire and early Christianity. The kingdom of Aksum had been founded before the time of Christ in what is now Eritrea and northern Ethiopia. It prospered as the crossroads for trade between the Roman Empire and India and became a Christian state during the 300's. By the mid-300's, Aksum controlled the major land and sea routes that linked Africa with Europe and Asia. Aksum declined after the 500's, but its Christian traditions survived and formed the basis for the Ethiopian Christian Church.



After the fall of Kush, a number of small kingdoms grew up in the Nile Valley region of Nubia. These kingdoms were prosperous agricultural states that kept in close contact with Christian Egypt through trade. Egyptian missionaries converted the Nubians to Christianity during the 500's. Christianity flourished in Nubia for hundreds of years, and Nubian religious influence extended westward over much of the neighboring territory.

The rise of Islam became one of the most important developments in African history. Islam emerged in Arabia during the early 600's. Within 100 years, Arab Muslims had built a huge empire that stretched from the Middle East, across northern Africa, and into Spain. The Muslims invaded Egypt in 639 and completed the conquest of all northern Africa by 710. The empire later broke up into smaller states, but ties of religion and trade continued to link the Muslims.

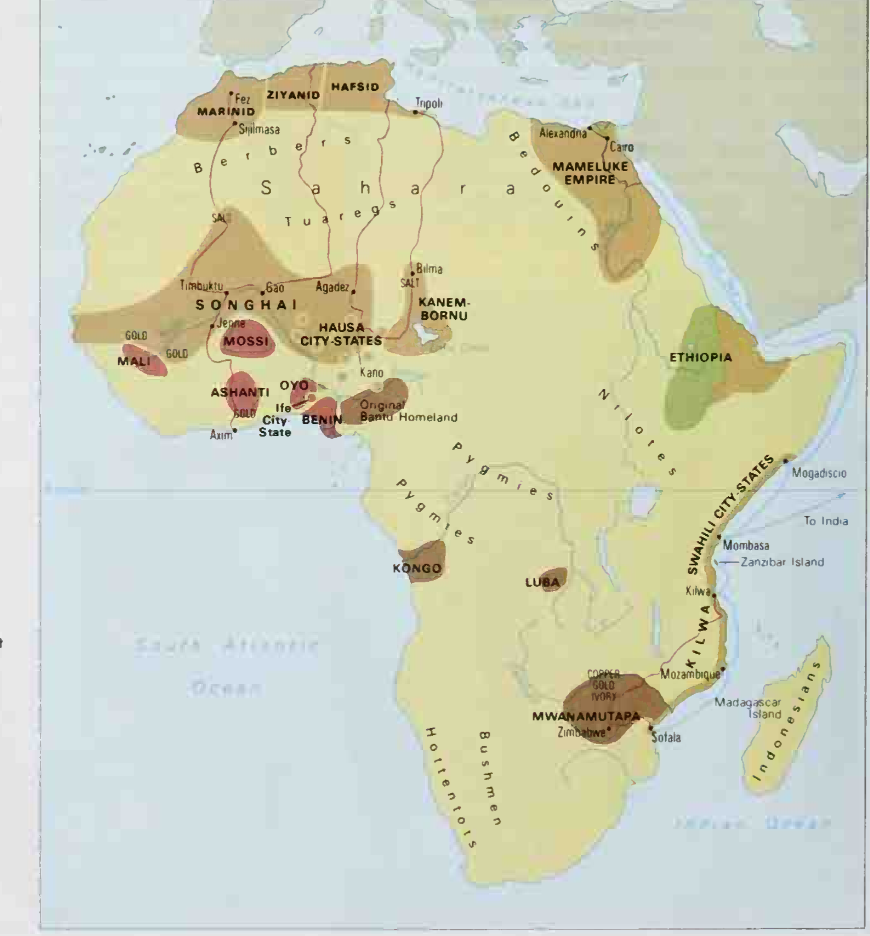
At first, most people under Muslim rule in northern Africa did not accept Islam. The conversion of northern Africans from Christianity or local religions to Islam took hundreds of years. South of the Sahara, Islam was spread mainly by Muslim merchants and traveling scholars. Camel caravans that crossed the Sahara brought the northern Muslims into contact with western Africa. Muslim traders who sailed the Indian Ocean converted the peoples living along the coasts of what are now Somalia, Kenya, and Tanzania.

The Muslims had far-reaching influence in Africa aside from the teaching of Islam. They honored learning and had collected and preserved much of the world's accumulated knowledge in such fields as science, phi-

Timothy Kendall

The civilization of Kush developed after 1000 B.C. and lasted until about A.D. 350 along the Nile River in what is now northern Sudan. Kush was an important trade center. It also served as a center for the exchange of ideas among peoples from the north and south and peoples from southwestern Asia. The Kush temple at the left shows the influence of Roman and Egyptian architecture.

losophy, geography, and history. The Muslims introduced into Africa their distinctive art forms. They taught reading and writing in Arabic to many Africans who could not read or write. Arabic became a common language shared by Africans of various ethnic groups. Muslim scholars established religious schools that attracted students from many parts of Africa.



Kingdoms in western Africa began to flourish about 1000, largely because of the growth of trade across the Sahara. Traders brought gold and kola nuts from western Africa to northern kingdoms such as those of the Hafsid, Marinid, and Ziyanid rulers. The traders exchanged the gold and kola nuts for salt and copper from Saharan mines, dried fruits from northern Africa, textiles from Europe, and finely crafted objects from the Middle East. Kingdoms at the southern edge of the Sahara gained power and wealth through the control of the Saharan trade. Such cities as Gao and Timbuktu became busy commercial centers. As the trade routes extended farther south, such kingdoms and states as Ashanti, Benin, Mossi, Oyo, and the Hausa city-states also became trade centers.

Ghana, one of the first great kingdoms of western Africa, had probably been founded during the 300's. The kingdom reached its height about 1000, when it covered parts of what are now Mali and Mauritania. During the 1200's, the Mali Empire replaced Ghana as the most powerful state in the west. It included parts of what are now Gambia, Guinea, Senegal, Mali, and Mauritania. By 1500, most of Mali came under the control of the Songhai Empire, a vast state that stretched from the Atlantic Ocean to what is now central Nigeria. East of Mali and Songhai lay Kanem. It had been founded during the 700's and lasted more than 1,000 years.

Eastern, central, and southern kingdoms. About 1100, a growing number of Arab Muslim traders began to settle on the Indian Ocean coast of what are now Kenya, Mozambique, Somalia, and Tanzania. They helped develop a thriving sea trade that linked eastern Africa with China, India, and Indonesia, and with countries bordering the Red Sea and the Persian Gulf. East coast ports exported gold, ivory, and other products in exchange for such goods as silk, cotton cloth, and porcelain. The east coast settlements eventually developed into a string of prosperous city-states, including Kilwa, Mogadiscio, Mombasa, and Sofala. The peoples of

Africa in the 1400's

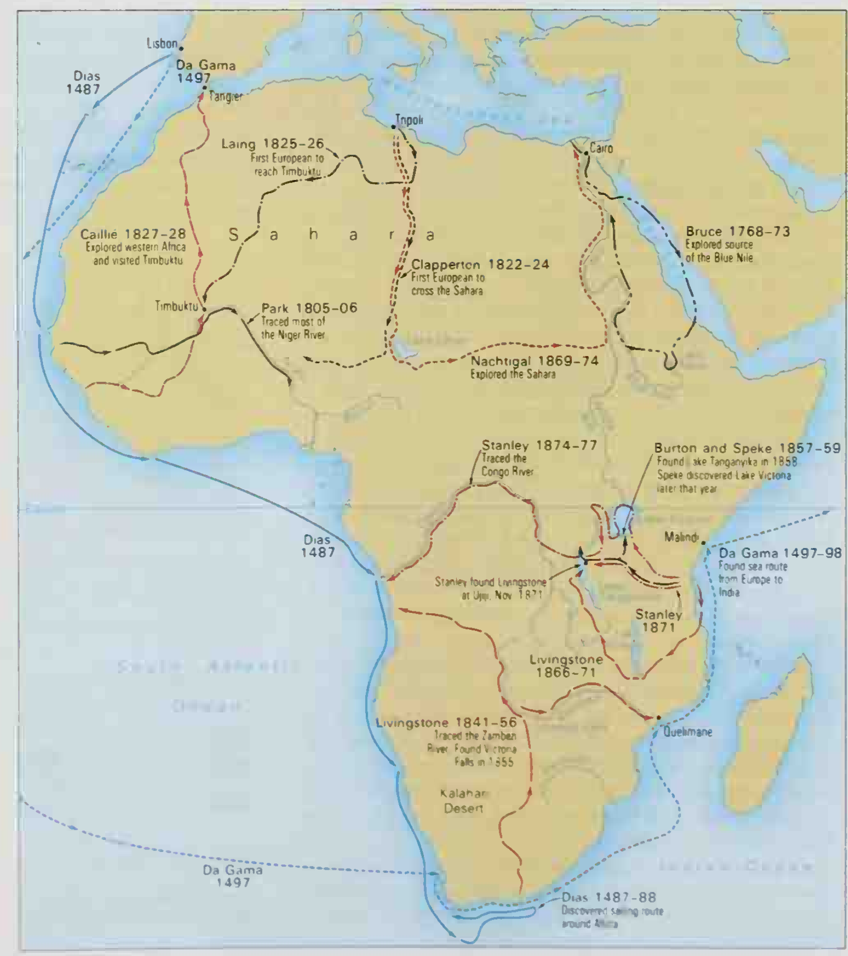
these city-states spoke Swahili. Their culture became a blend of local black African and Islamic traditions.

Many kingdoms grew up in the forests and grasslands of central and southern Africa. Some of the most powerful kingdoms established elaborate systems of government and rich traditions in sculpture, music, and oral poetry. One of the largest kingdoms, the Kongo, began to spread out from the mouth of the Congo River during the 1400's. The Kongo lasted until the early 1700's. Another major kingdom that arose in the 1400's was Luba, in what is now southern Congo (Kinshasa). Also during the 1400's, the Karanga people established the Mwanamutapa Empire in what are now Mozambique and Zimbabwe. The Changamire Empire conquered the Mwanamutapa during the late 1400's. The city of Zimbabwe served as the capital of both empires.



The beginnings of European control. During the 1400's, the Portuguese began to explore the west coast of Africa. They were interested in Africa's gold trade and so established trading posts in Gambia, the Gold Coast (now Ghana), and other west coast lands. They also tried to convert the rulers of the Kongo and other kingdoms to Christianity. Soon after the Portuguese arrived in western Africa, they began to ship black Africans to Europe as slaves. In 1497 and 1498, Vasco da Gama led a Portuguese expedition that sailed around the Cape of Good Hope, along the east coast of Africa, and on to India. The Portuguese won control of the city-states of eastern Africa during the 1500's. During the 1600's, the Dutch took over many of Portugal's west coast trading posts. They also established Cape Town at the southern tip of Africa in 1652.

Africa had shipped slaves to Asia and Europe long before the Portuguese arrived. But the establishment of European plantations in North and South America during the 1500's led to a much greater demand for slaves. By the 1800's, Europeans had brought as many as 10 million slaves from western Africa to the Americas. About 500,000 of the slaves were shipped to what is now the United States. Arab and African traders on Africa's east coast shipped slaves to Zanzibar and countries bordering the Red Sea and the Persian Gulf. See **African Americans** (Beginning of the slave trade); **Slavery.**

The trade in gold and slaves brought more wealth and power to some African forest kingdoms, such as Ashanti in what is now Ghana. European traders intro-

European exploration of Africa

WORLD BOOK map

duced cassava and corn into Africa. These foods became important crops. The traders also introduced Africans to guns, which the Africans eventually used in wars against one another or against the Europeans.

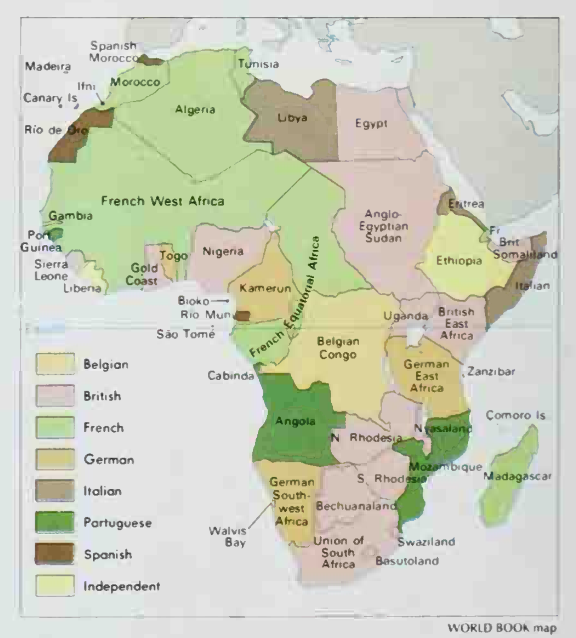
During the late 1700's, Europeans began to explore the African interior. They wanted to spread Christianity and to develop new trade ties based on minerals, palm oil, and other raw materials for industry. Europeans who opposed slavery hoped that the new trade products would help end the slave trade. Great Britain outlawed the slave trade in 1807. In 1808, the United States began prohibiting the import of slaves from Africa.

European influence and control in Africa also grew through military means. Much of northern Africa had been part of the Turkish Ottoman Empire since the 1500's. But as Turkish power declined, European powers fought for control of the region. During the 1800's, France gained Algeria and Tunisia, and Britain won Egypt. In southern Africa, the Dutch began to move inland from their settlement at Cape Town after 1700. As the Dutch spread out, they fought and conquered the local black Africans.

In spite of the growing European presence, large parts of Africa had little or no contact with Europe until the mid-1800's or the late 1800's. Many major events in African history did not involve Europeans. During the 1700's and 1800's, Muslim religious reformers led a series of "holy wars" in western Africa to strengthen the influence of Islam. By 1860, new Muslim empires ruled most of the western grasslands. In southern Africa, well-trained Zulu armies won a series of wars against neighboring peoples during the early 1800's.

Colonial rule. As Europeans became increasingly involved in African economic affairs, mainly through trade, they gained more and more political control over parts of the continent. By the 1880's, there were intense rivalries among the European powers as they staked out claims to profitable parts of Africa. By 1914, Belgium, France, Germany, Great Britain, Italy, Portugal, and Spain had divided almost all Africa among themselves. Only Ethiopia and Liberia remained independent.

In some parts of Africa, colonial rule was established peacefully by treaties between the Europeans and African chiefs. But other Africans resisted European control. For example, they staged violent uprisings against the British in Nigeria and what is now Ghana, against the French in western and northern Africa, and against the Germans in what are now Tanzania and Namibia. By the mid-1920's, however, Europeans strongly controlled most of Africa.



Colonial rule lasted a relatively short time—only until the 1960's in most of Africa. However, it brought major changes to Africa. Colonial rule created new political units with boundaries that cut across ethnic homelands in some cases. It gave foreigners control over African government affairs. The Christian missionaries that accompanied colonial rule challenged religious and social traditions that had long been part of African life. Colonial rule tied Africa to an economic system based on world needs rather than on local needs. African farmers and miners had to produce goods for world markets and raw materials for European industries.

Many Africans look upon the period of colonial rule as a humiliating experience in their history. But some Africans believe that the period brought improvements. For example, Europeans provided additional medical services and helped control certain diseases. Colonial schools taught millions of Africans how to read and write in European languages.

The movement to independence. Many Africans resisted colonial rule from the beginning. During the early 1900's, organized groups in some African colonies had already begun to demand self-government. But not until after World War II (1939-1945) did the demands for independence become a powerful mass movement.

In many colonies, Africans who had been educated in Europe led the organizations that called for self-government. Supported by the masses, these organizations staged strikes, boycotts, and rallies. In some cases, the anticolonial feelings erupted in riots, terrorist attacks, and armed rebellions. A revolt against the French in Algeria broke out in 1954. But because of the large number of French settlers there, the revolt lasted eight years before the country won independence. In 1957, the Gold Coast became the first black African colony to gain its freedom. It won independence from Britain and took the name Ghana. By the mid-1960's, Britain, Belgium, and France had freed most of their African colonies.

Southern Africa presented the most serious obstacles to the independence movement. Portugal fought costly wars in Angola and Mozambique before granting them freedom in 1975. In Rhodesia, blacks fought for years against white-minority rule. A government with a majority of blacks was finally elected in 1979. The following year, Britain recognized Rhodesia's independence, and

Africa in 1914 had only two independent countries—Ethiopia and Liberia. The rest of the continent was under colonial rule by European powers.

the country was renamed Zimbabwe. South Africa's control over the territory of Namibia (called South West Africa until 1968) became an international issue during the mid-1900's. Most nations considered South Africa's control of Namibia to be illegal. In March 1990, Namibia became an independent country.

South Africa itself had become fully independent of the United Kingdom in 1931. Black Africans formed a large majority of the population of South Africa. However, white people controlled the country's government and excluded black Africans from government affairs. The white government also developed a rigid system of racial separation called *apartheid.* Most of the black Africans believed that they still suffered from a form of colonialism.

The South African government's apartheid policies of discrimination and segregation enraged black African nations and drew criticism from most other countries in the world. Beginning in the 1970's, the South African government gradually ended the social segregation and legal aspects of apartheid. But black Africans remained politically excluded and were not even allowed to vote. In the early 1990's, however, South Africa repealed most of its remaining apartheid laws. In April 1994, South Africa held elections in which black Africans were allowed to vote. In the elections, black Africans gained control of the government.

Africans who won independence rejoiced, but they soon found that freedom did not solve all their problems. Leaders in many of the new nations could not handle crises that arose in political, social, and economic affairs. Military officers overthrew civilian governments in many countries and set up military governments. New civilian governments often followed these military governments. In a few countries, military dictatorships emerged. Civil wars broke out in Congo (Kinshasa), Nigeria, Chad, and other countries.

Africa today continues to face serious problems, including poverty, illiteracy, disease, and food shortages. Severe droughts contribute greatly to the food shortage. One of the worst droughts in history struck Africa in the early 1980's. Many Africans died of starvation and related causes. The drought was particularly devastating in Ethiopia. Another drought in the early 2000's led to widespread food shortages in southern Africa.

In the 1990's and early 2000's, the AIDS epidemic reached disastrous levels in Africa, especially in areas south of the Sahara. The disease has become the continent's leading cause of death. By the early 2000's, more than 17 million AIDS-related deaths had occurred in Africa, and more than 26 million Africans were living with the AIDS virus.

In many African countries, economic and social development is handicapped by a dependence on one or two products as sources of national income. Inflation in industrialized nations has caused Africa to pay more for the manufactured goods it imports than it receives for the raw materials it exports. Ethnic rivalries continue to divide many countries. Territorial disputes have led to frequent wars between nations.

Many people see signs of hope in Africa in spite of all its problems. More Africans than ever are attending school and developing skills needed to improve their standard of living. Valuable mineral resources in Angola, Gabon, Nigeria, and other countries may lead to greater economic strength.

African nations are also trying to work together to solve common problems. Cooperation is the ideal behind the movement of *pan-Africanism,* which promotes the unity of African countries. The Organization of African Unity (OAU), an association of African states, worked to build ties among African peoples and helped end colonial and white minority rule. It existed from 1963 to 2002, when it was replaced by the African Union (AU). The AU, which includes almost all African countries, works to achieve greater political, social, and economic cooperation among African countries and peoples. Africans have also formed several regional groups, including the Southern African Development Community and the Economic Community of West African States, to promote cooperation in economic affairs. In addition, in the early 2000's, African leaders began implementing an economic development plan called the New Partnership for Africa's Development. Although these various efforts cannot solve all of Africa's problems, they offer

Important dates in Africa

c. 2,000,000 B.C. The earliest human beings may have lived in eastern Africa.

c. 5000 B.C. People in northern Africa practiced farming.

c. 4000 B.C. The Sahara began to turn into a desert.

c. 3100 B.C. Upper and Lower Egypt became one country.

c. 2000 B.C. The Kingdom of Kush arose south of Egypt.

30 B.C. The Roman Empire controlled northern Africa.

c. A.D. 1 Bantu-speaking peoples began southward migrations.

300's The Kingdom of Aksum became a Christian state.

500's The Nubian kingdoms were converted to Christianity.

639-710 Arab Muslims conquered northern Africa.

1000-1500 Large kingdoms were established in Africa south of the Sahara.

1400's The Portuguese began to explore Africa's west coast.

1652 The Dutch founded Cape Town.

Late 1700's Europeans began to explore the African interior.

1880's European governments began to claim parts of Africa.

1920's European colonial rule was firmly established in Africa.

1950's-1960's Most European colonies in Africa became independent.

1975 Portugal, the last European country with large African holdings, gave up its remaining colonies.

1979 Black Africans in Rhodesia (now known as Zimbabwe) gained control of the country's government, ending white-minority rule there.

1980's One of the worst droughts in history struck Africa. Ethiopia was especially hard-hit.

1990 Namibia gained independence, ending its white-minority rule by South Africa.

1994 Blacks in South Africa gained control of the country's government, ending white-minority rule there.

AP/Wide World

South Africa's first elections open to all races, held in 1994, drew long lines of voters to the polls. In the elections, blacks gained control of the government from the white minority. Previously, blacks, who make up a majority of the nation's population, could not vote.

hope that cooperation will lead to progress and greater stability throughout the continent. After independence, one-party political systems were established in many African countries. But in the early 1990's, a number of these countries adopted multiparty systems. Samuel Decalo; Kennell A. Jackson, Jr.; Kenneth J. Perkins; and Hartmut S. Walter

African American literature is literature written by black Americans of African descent. Its themes include the exploration of black identity, the condemnation of racism, and the celebration of the unique aspects of African American culture.

Early works. The earliest surviving works of African American literature date from the mid-1700's and were written by Africans brought to America as slaves. The oldest example is considered to be "Bars Fight," a poem about an Indian raid on a Massachusetts town. Lucy Terry, a young New England slave, composed the poem, which was handed down orally, in 1746. In the late 1700's, Phillis Wheatley, a Boston slave, became the first important black poet. Her *Poems on Various Subjects, Religious and Moral* (1773) was the first book by an African American to be published.

The 1800's. Before the American Civil War (1861-1865), many black writers were fugitive slaves. They described their experiences on plantations in an attempt to convince readers that slavery was immoral and to show the courage, humanity, and intelligence of the slaves. The most important slave autobiography of the period is the *Narrative of the Life of Frederick Douglass* (1845). Douglass became the leading spokesman for American blacks in the 1800's. *Incidents in the Life of a Slave Girl* (1861), by Harriet Ann Jacobs, is the only autobiography about the unique hardships suffered by women slaves.

The first published African American fiction appeared in the mid-1800's. This fiction included such novels as *Clotel, or The President's Daughter* (1853), by William Wells Brown; and *Our Nig* (1859), by Harriet E. Wilson. They were similar in content to slave autobiographies. *The Garies and Their Friends* (1857), by Frank J. Webb, is a novel that describes the problems of a free family living in the North. *Blake* (1861-1862), by Martin Robinson Delany, is a novel about a free black man who organizes a slave rebellion.

After slavery was abolished in 1865, African American authors wrote in many literary forms to protest race discrimination. In the 1890's and early 1900's, Paul Laurence Dunbar was acclaimed for his romantic poems in black dialect. However, some of his verses imply bitter social criticism. Charles Waddell Chesnutt sought to revise the negative images of former slaves by portraying them as intelligent and resourceful in his realistic short stories and novels. Chesnutt is considered to be the first major African American writer of fiction. Such black women writers as Frances Harper and Pauline Hopkins challenged both racism and sexism in their novels.

The 1900's. African American ethnic pride and creativity flourished during the 1920's. The period's exceptional outpouring of black literature came to be called the Harlem Renaissance because it began in Harlem, a district of New York City. The movement was also called the New Negro, after the title of a book by educator and writer Alain Locke. Important African American writers of the time include Sterling A. Brown, James Weldon Johnson, Countee Cullen, Langston Hughes, Claude McKay, Jean Toomer, Jesse Redmon Fauset, and Zora Neale Hurston.

In the mid-1900's, much African American literature exposed the bleak conditions of black life and condemned discrimination against the poor of all races. Richard Wright's *Native Son* (1940) and Ralph Ellison's *Invisible Man* (1952) both describe a black man's quest for identity in a hostile world. James Baldwin explored the same theme in novels, essays, and dramas set primarily in the urban North.

In 1950, Gwendolyn Brooks became the first African American to be awarded a Pulitzer Prize for poetry. Like many black writers of the time, Brooks examined the impact of race and poverty on the African American's pursuit of the American dream.

During the 1960's and 1970's, many blacks gave up hopes of an integrated society and began to call for a separate black culture. A number of poets and dramatists rejected traditional literary techniques and themes and developed their own forms of self-expression. These writers include LeRoi Jones (now Amiri Baraka), Don L. Lee (now Haki Madhubuti), Nikki Giovanni, Sonia Sanchez, Etheridge Knight, Douglas Turner Ward, and Ed Bullins.

Recent developments. In the late 1900's, many black novelists produced works of myth, ritual, and magic realism to reflect on the legacies of slavery and racial prejudice. In 1983, Alice Walker won the Pulitzer Prize for *The Color Purple,* a novel about an unwed mother forcibly separated from her children. August Wilson emerged as a leading playwright. His major plays trace the black experience in the United States in the 1900's. In 1993, Toni Morrison became the first African American to be awarded the Nobel Prize for literature. Yusef Komunyakaa won the 1994 Pulitzer Prize for poetry for *Neon Vernacular.* From 1993 to 1995, Rita Dove served as the first African American poet laureate.

The history of African Americans is largely the story of their struggle for equality and freedom. This mural of black Americans includes slave leader Nat Turner, *upper left,* Revolutionary War soldier Peter Salem (below Turner), bearded abolitionist Frederick Douglass, agricultural researcher George Washington Carver (with test tube), and singer Marian Anderson, *far right center.*

African Americans

African Americans are Americans mostly or partly of African descent. Approximately 35 million African Americans live in the United States. They make up 12 percent of the nation's total population and, in number, trail only Hispanic Americans among minority groups. About half of all black Americans live in the Southern States. Most of the rest live in large cities in the East, Midwest, and West.

Most African Americans have used five terms to refer to themselves. The terms *Negro* (which means *black* in Spanish and Portuguese) and *colored* were commonly used until the mid-1960's. These terms referred to the dark brown skin color of many black Americans. Since then, most black Americans have chosen to express deep pride in their color or origin by calling themselves *blacks, Afro-Americans,* or *African Americans.*

The majority of American blacks trace their origin to an area in western Africa that was controlled by three great and wealthy black empires from about the A.D. 300's to the late 1500's. These empires—Ghana, Mali, and Songhai—thrived on trade and developed efficient governments. During the early 1500's, European nations began a slave trade in which blacks from western Africa were brought to European colonies in the Americas. For about the next 300 years, millions of enslaved black Africans were shipped across the Atlantic Ocean to North and South America. About 500,000 of the Africans were brought to what is now the United States.

The history of African Americans is largely the story of their struggle for freedom and equality. From the 1600's until the American Civil War (1861-1865), most black Americans worked as slaves throughout the South. They did much to help Southern agriculture expand. At the same time, free blacks helped develop industry in the North. After 1865, when slavery was finally abolished in the nation, black Americans briefly gained their civil rights during a period called Reconstruction. But after Reconstruction, they again lost those rights and suffered from widespread segregation and poverty. The determined efforts of African Americans to achieve equality and justice led to the start of a strong civil rights movement in the United States in the 1950's.

Alton Hornsby, Jr., the contributor of this article, is Fuller E. Callaway Professor of History at Morehouse College and editor of The Journal of Negro History.

The lives of African Americans have improved since the 1950's. But many still suffer from segregation and poverty, discrimination in jobs and housing, and other problems. At the same time, however, more black Americans are making important contributions in all areas of American life.

This article describes the African background of black Americans and traces their history since their arrival in North America. The section at the end of the article lists the many related articles in *World Book.*

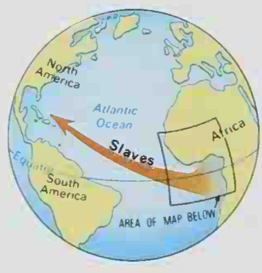
The African background

The cultural heritage. The ancestors of most American blacks came from an area of Africa known as the Western Sudan. This area was about as large as the United States, not including Hawaii and Alaska. It extended from the Atlantic Ocean in the west to Lake Chad in the east and from the Sahara in the north to the Gulf of Guinea in the south.

From about the A.D. 300's to 1591, three highly developed black empires, in turn, controlled all or most of the Western Sudan. They were Ghana, Mali, and Songhai. Their economy was based on farming, on mining gold, and on trade with Arabs of northern Africa.

Ghana ruled much of the Western Sudan from the 300's to the mid-1000's. The Ghanaians became the first people in western Africa to smelt iron ore. They made arrows, swords, and other weapons of iron, which helped them conquer nearby nations.

In 1235, the Malinke people of Mali began to develop the second great black African empire of the Western Sudan. By 1240, they controlled all Ghana. The Mali Empire's most famous ruler was Mansa Musa, who reigned from 1312 to about 1337. Mansa Musa encouraged the practice of Islam, the religion of the Muslims. Under his rule, Mali reached its height of wealth, political power, and cultural achievement.



Beginning in the 1400's, the Songhai Empire gained control of most of northwestern Africa south of the Sahara, including much of Mali. Under Askia Muhammad, who ruled Songhai from 1493 to 1528, the empire had a well-organized central government and excellent universities in such cities as Timbuktu and Jenne. Like Mansa Musa, Askia encouraged his people to practice the Islamic faith. Invaders from Morocco conquered Songhai in 1591.

Some ancestors of black Americans lived in smaller nations in the Western Sudan. These nations included Oyo, Benin, Dahomey, and Ashanti. Their economies also depended on farming, trade, and gold mining. For more details on the major black African empires, see **Ghana Empire; Mali Empire; Songhai Empire.**

Beginning of the slave trade. Africans had practiced slavery since ancient times. In most cases, the

slaves had been captured in warfare and sold to Arab traders of northern Africa. Portugal and Spain became increasingly involved in the African slave trade during the early 1500's, after they had established colonies in the Americas. Portugal acquired African slaves to work on sugar plantations that its colonists developed in Brazil. Spain used slaves on its sugar plantations in the West Indies. During the early 1600's, the Netherlands, France, and England also began to use African slaves in their American colonies.

The Europeans obtained slaves from black Africans who continued to sell their war captives or trade them for rum, cloth, and other items, especially guns. The Africans needed the guns for use in their constant warfare with neighboring peoples.

The slave trade took several triangular routes. Over one route, ships from Europe transported manufactured goods to the west coast of Africa. There, traders exchanged the goods for slaves. Next, the slaves were carried across the Atlantic Ocean to the West Indies and sold for huge profits. This part of the route was called the *Middle Passage.* The traders used much of their earnings to buy sugar, coffee, and tobacco in the West Indies. The ships then took these products to Europe.

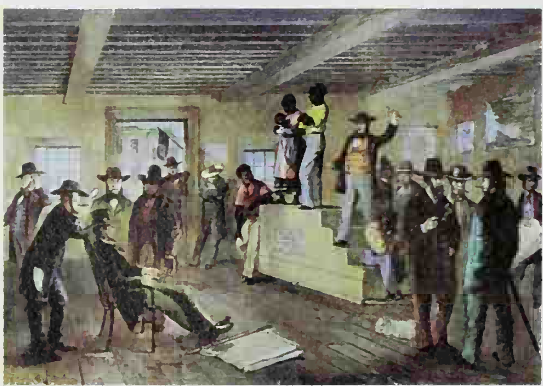
On another triangular route, ships from the New England Colonies carried rum and other products to Africa, where they were exchanged for slaves. The ships then transported the slaves to the West Indies to be sold. The slave traders used some of their profits to buy sugar and molasses, which they took back to New England and sold to rum producers.

The slave trade was conducted for profit. The captains of slave ships therefore tried to deliver as many healthy slaves for as little cost as possible. Some captains used a system called *loose packing* to deliver slaves. Under that system, captains transported fewer slaves than their ships could carry in the hope of reducing sickness and death among them. Other captains preferred *tight packing.* They believed that many blacks would die on the voyages anyway and so carried as many slaves as their ships could hold.

Most slave ship voyages across the Atlantic took several months. The slaves were chained below deck all day and all night except for brief periods of exercise. Their crowded conditions led to the chief horrors of the Middle Passage—filth, stench, disease, and death.

The Atlantic slave trade operated from the 1500's to the mid-1800's. No one knows how many Africans were enslaved during this period. The most reliable estimates suggest about 10 million blacks. Of this total, what is now the United States received about 5 percent.

The years of slavery



Some scholars believe that the first blacks in America came with the expeditions led by Christopher Columbus, starting in 1492. Black slaves traveled to North and South America with French, Portuguese, and Spanish explorers throughout the 1500's.

The best-known black to take part in the early explorations of North America was a slave named Estevanico. In 1539, he crossed what are now Arizona and New Mexico on an expedition sent by Antonio de Mendoza, ruler of Spain's colony in America.

Colonial times. The first blacks in the American Colonies were brought in, like many lower-class whites, as *indentured servants.* Most indentured servants had a contract to work without wages for a master for four to seven years, after which they became free. Blacks brought in as slaves, however, had no right to eventual freedom. The first black indentured servants arrived in Jamestown in the colony of Virginia in 1619. They had been captured in Africa and were sold at auction in Jamestown. After completing their service, some black indentured servants bought property. But racial prejudice among white colonists forced most free blacks to remain in the lowest level of colonial society.

The first black African slaves in the American Colonies also arrived during the early 1600's. The slave population increased rapidly during the 1700's as newly established colonies in the South created a great demand for plantation workers.

By 1750, about 200,000 slaves lived in the colonies. The majority lived in the South, where the warm climate and fertile soil encouraged the development of plantations that grew rice, tobacco, sugar cane, and later cotton. Most plantation slaves worked in the fields. Oth-

Granger Collection

Slave trading became increasingly profitable throughout the South from the time the first slaves arrived in the early 1600's. Buyers often paid more than $1,000 for a skilled, healthy slave. Many slaves were sold at auctions like this one in Virginia.

Granger Collection

Crispus Attucks, *center,* was a leader of the patriot mob that was fired upon by British troops in the Boston Massacre of 1770. Attucks and many other free blacks who lived in the North opposed British rule in the American Colonies.

ers were craftworkers, messengers, and servants.

Only 12 percent of slaveowners operated plantations that had 20 or more slaves. But more than half of all the country's slaves worked on these plantations. Most of the other slaveowners had small farms and only a few slaves each. Under arrangements with their masters, some slaves could hire themselves out to work for other whites on farms or in city jobs. Such arrangements brought income to both the slaves and the masters.

The cooler climate and rocky soil of the Northern and Middle colonies made it hard for most farmers there to earn large profits. Many slaves in those colonies worked as skilled and unskilled laborers in factories, homes, and shipyards and on fishing and trading ships.

During the mid-1600's, the colonies began to pass laws called *slave codes.* In general, these codes prohibited slaves from owning weapons, receiving an education, meeting one another or moving about without the permission of their masters, and testifying against white people in court. Slaves received harsher punishments for some crimes than white people. A master usually received less punishment for killing a slave than for killing a free person for the same reason. Slaves on small farms probably had more freedom than plantation slaves, and slaves in urban areas had fewer restrictions in many cases than slaves in rural areas.

By 1770, there may have been 40,000 or more free blacks in the American Colonies. They included runaway slaves, descendants of early indentured servants, and black immigrants from the West Indies. Many free blacks opposed British rule. One of the best-known African American patriots was Crispus Attucks, who died in the Boston Massacre of 1770 while mocking the presence of British soldiers.

During the Revolutionary War in America (1775-1783), most blacks probably favored the British. They believed that a British victory would offer them their earliest or best chance for freedom. But about 5,000 blacks fought on the side of the colonists. Most of them were free blacks or slaves from the Northern and Middle colonies. Black heroes of the war included Peter Salem and Salem Poor of Massachusetts, who distinguished themselves in the Battle of Bunker Hill in 1775.

The growth of slavery. By the early 1800's, more than 700,000 slaves lived in the South. They accounted for about a third of the region's people. Slaves outnumbered whites in South Carolina and made up over half the population in both Maryland and Virginia.

Slavery began to develop even deeper roots in the South after Eli Whitney of Massachusetts invented his cotton gin in 1793. This machine removed the seeds from cotton as fast as 50 people working by hand and probably contributed more to the growth of slavery than any other development. Whitney's gin enabled farmers to meet the rapidly rising demand for cotton. As a result, the Southern cotton industry expanded, and cotton became the chief crop in the region. The planters needed more and more workers to pick and bale the cotton, which led to large increases in the slave population. The thriving sugar cane plantations of Louisiana also used many slaves during the first half of the 1800's. By 1860, about 4 million slaves lived in the South.

Numerous slaves protested against their condition. They used such day-to-day forms of rebellion as destroying property, running away, pretending illness, and disobeying orders. Major slave protests included armed revolts and mutinies. The most famous of about 200 such revolts was led by Nat Turner, a slave and preacher. The revolt broke out in 1831 in Southampton County in Virginia. The rebels killed about 60 white people before being captured. The best-known slave mutiny occurred in 1839 aboard the *Amistad,* off the coast of Cuba. A group of Africans, led by Cinqué, brought the vessel to Long Island in New York. The slaves were given their freedom soon afterward.

Slaves received beatings or other physical punishment for refusing to work, attempting to run away, or participating in plots or rebellions against their owners. Some slaves were executed for rebelling.

Free blacks. The Revolutionary War helped lead to new attitudes about slavery, especially among whites in the North. The war inspired a spirit of liberty and an appreciation for the service of the black soldiers. Partly for this reason, some Northern legislatures adopted laws during the late 1700's that provided for the immediate or gradual end of slavery. Another reason for such laws

Granger Collection

Granger Collection

The production of cotton increased rapidly in the South after Eli Whitney invented a faster way of cleaning cotton in 1793. Whitney's cotton gin, *left,* could clean as much cotton in a day as could 50 people working by hand and helped meet the growing demand for cotton. More workers were needed on plantations, *right,* which led to a huge growth in the slave population.

was simply that slaves had no essential role in the main economic activities of the North.

The census of 1790 revealed that the nation had about 59,000 free blacks, including about 27,000 in the North. By the early 1800's, most Northern states had taken steps to end slavery. Besides former slaves freed by law, free blacks included those who had been freed by their masters, who had bought their freedom, or who had been born of free parents.

After the Revolutionary War, numerous free blacks found jobs in tobacco plants, textile mills, and other factories. Some worked in shipyards, on ships, and later in railroad construction. Many free blacks became skilled in carpentry and other trades. Some became merchants and editors. The best-known editors were Samuel Cornish and John Russwurm, who helped start the first black newspaper, *Freedom's Journal*, in 1827.

Most whites treated free blacks as inferiors. Many hotels, restaurants, theaters, and other public places barred them. Few states gave free blacks the right to vote. The children of most free blacks had to attend separate schools. Some colleges and universities, such as Bowdoin and Oberlin, admitted black students. But the limited number of admissions led to the opening of black colleges, including Lincoln University in Pennsylvania in 1854 and Wilberforce University in Ohio in 1856.

In both the North and the South, churches either banned blacks or required them to sit apart from white people. As a result, some blacks set up their own churches. In 1816, Richard Allen, a black Philadelphia minister, helped set up the African Methodist Episcopal Church, the first black denomination in the country.

The rising number of free blacks alarmed many whites and led to further restrictions on their activities. In parts of New England, free blacks could not visit any town without a pass. They also needed permission to entertain slaves in their homes. In the South, free blacks could be enslaved if caught without proof that they were free. Fears that free blacks would lead slave revolts encouraged almost all states to pass laws severely limiting the right of free blacks to own weapons.

Increasing concern over the large number of free blacks led to the founding of the American Colonization Society in 1816. The society was sponsored by well-known supporters of slavery, including U.S. Representatives John C. Calhoun of South Carolina and Henry Clay of Kentucky. Their plan was to lessen "the race problem" by transporting free blacks on a voluntary basis to Africa. In 1822, the society established the black American colony of Liberia on the continent's west coast. In 1847, Liberia became the first self-governing black republic in Africa. Although free blacks suffered from discrimination, most felt that the United States was their home. As a result, only about 12,000 of them had volunteered to settle in Liberia by 1850.

In spite of their inferior position, a number of free blacks won wide recognition during the late 1700's and early 1800's. For example, Jupiter Hammon and Phillis Wheatley gained fame for their poetry. Newport Gardner distinguished himself in music. Benjamin Banneker, a mathematician, published outstanding almanacs. Notable black ministers included Absalom Jones in the North and George Liele and Andrew Bryan in the South. Paul Cuffe and James Forten gained great wealth in business. Tom Molineaux became known for his boxing skills.

By 1860, the nation had about 490,000 free blacks. But most of them faced such severe discrimination that they were little better off than the slaves.

The antislavery movement. Many white Americans, particularly Northerners, felt that slavery was wicked and violated the ideals of democratic government. However, plantation owners and other supporters of slavery regarded it as natural to the Southern way of life. They also argued that Southern culture introduced the slaves to Christianity and helped them become "civilized." Most white Southerners held such beliefs by 1860, though less than 5 percent of them owned slaves and only about half the slaveowners had more than five slaves. In addition, Southern farmers insisted that they could not make money growing cotton without cheap slave labor.

The Southern States hoped to expand slavery as new states were admitted to the Union. However, the Northern States feared they would lose power in Congress permanently if more states that permitted slavery were admitted. The North and the South thereby became increasingly divided over the spread of slavery.

The slavery issue created heated debate in Congress after the Territory of Missouri applied for statehood in 1818. At the time, there were 11 slave states, in which slavery was allowed, and 11 free states, in which it was prohibited. Most Missourians supported slavery, but many Northern members of Congress did not want Missouri to become a slave state. In 1820, Congress reached a settlement known as the Missouri Compromise. This measure admitted Missouri as a slave state, but it also called for Maine to enter the Union as a free state. Congress thus preserved the balance between free and slave states at 12 each.

New, aggressive opponents of slavery began to spring up in the North during the 1830's. Their leaders included William Lloyd Garrison, Lucretia Mott, Lewis Tappan, and Theodore Dwight Weld. During the 1830's and 1840's, these white abolitionists were joined by many free blacks, including such former slaves as Frederick Douglass, Henry Highland Garnet, Harriet Tubman, and Sojourner Truth.

Most of the abolitionist leaders attacked slavery in writings and public speeches. Garrison began to publish an antislavery newspaper, *The Liberator*, in 1831. Douglass, the most influential black leader of the time, started an abolitionist newspaper called the *North Star* in 1847. Tubman and many other abolitionists helped Southern slaves escape to the free states and Canada. Tubman returned to the South 19 times and personally led about 300 slaves to freedom. She and others used a network of routes and housing to assist the fleeing blacks. This network became known as the *underground railroad.*

The deepening division over slavery. After 1848, Congress had to deal with the question of whether to permit slavery in the territories that the United States gained from Mexico as a result of the Mexican War (1846-1848). The territories covered what are now California, Nevada, Utah, and parts of four other states. Following angry debates among the members of Congress, Senators Henry Clay of Kentucky and Daniel Webster of Massachusetts helped work out a series of measures that became known as the Compromise of 1850. The Compromise allowed slavery to continue but prohibited

the slave trade in Washington, D.C. A key measure in the Compromise admitted California to the Union as a free state. Another agreement gave the residents in the other newly acquired areas the right to decide for themselves whether to allow slavery. The Compromise included a federal fugitive slave law that was designed to help slaveowners get back runaway slaves.

The Compromise of 1850 briefly ended the heated arguments in Congress over the slavery issue. However, the abolitionist movement and the hostility between the North and the South continued. The publication of Harriet Beecher Stowe's antislavery novel *Uncle Tom's Cabin* (1851-1852) greatly increased the tensions between Northerners and Southerners. In addition, attempts by Northerners to stop enforcement of the fugitive slave law further angered Southerners.

The quarrel over slavery flared again in Congress in 1854, when it passed the Kansas-Nebraska Act. This law created two federal territories, Kansas and Nebraska, and provided that the people of each territory could decide whether to permit slavery. Most Nebraskans opposed slavery. However, bitter, bloody conflicts broke out between supporters and opponents of slavery in Kansas. In 1856, for example, the militant abolitionist John Brown led a raid against supporters of slavery in a small settlement on Pottawatomie Creek in Kansas. Brown's group killed five men and focused the nation's attention on the conflict in the territory, which became known as "Bleeding Kansas." In the end, Kansas joined the Union as a free state in 1861.

Supporters of slavery won a major victory in 1857, when the U.S. Supreme Court issued its ruling in the case of *Dred Scott v. Sandford.* In the Dred Scott Decision, the court denied the claim of Scott, a slave, that his residence in a free state and territory for a time made him free. The court also declared that no black—free or slave—could be a U.S. citizen. In addition, it stated that Congress had no power to ban the spread of slavery.

Tension in the South increased again in 1859, when John Brown led another abolitionist group in seizing the United States arsenal at Harpers Ferry in Virginia (now West Virginia). Federal troops quickly captured Brown, and he was executed later that year. But his raid helped convince many Southerners that the slavery issue would lead to fighting between the North and the South.

The end of slavery

Slavery became a major issue in the U.S. presidential election of 1860. Many Democrats in the North opposed the spread of slavery, but Democrats in the South favored it. Each group nominated its own candidate for President, thereby splitting their party. Most Republicans opposed the expansion of slavery. They chose Abraham Lincoln of Illinois as their presidential candidate. In November 1860, he was elected President.

The Civil War. Southerners feared that Lincoln would limit or end slavery. On Dec. 20, 1860, South Carolina *seceded* (withdrew) from the Union. Early in 1861, six other Southern states seceded. The seceded states took the name Confederate States of America. On April 12, 1861, Confederate troops attacked Fort Sumter, a United States military base in South Carolina, and the American Civil War began. Four more slave states joined the Confederacy soon afterward. Four other slave states—Missouri, Kentucky, Maryland, and Delaware—remained loyal to the Union.

At the start of the Civil War, Lincoln's chief concern was to preserve the Union, not to end slavery. He therefore refused requests of African Americans to join the Union Army. He felt that their participation in the war could lead more slave states to secede. Lincoln also knew that many Northerners were hostile toward blacks and so might oppose the use of black troops.

A number of developments gradually persuaded Lincoln to make the war a fight against slavery. For example, some Union military commanders, without the President's consent, had freed the slaves in areas they had conquered. Furthermore, abolitionists and black leaders urged that the war be fought to end slavery, and they demanded the use of black troops. Most importantly, the war was going badly for the Union. By fighting against slavery, Lincoln hoped to strengthen the war effort in the North and weaken it in the South.

In March 1862, Lincoln gave Congress a plan for the gradual freedom of slaves. The plan included payment for the slaveowners. In April, Lincoln approved legis-

Bloody conflicts broke out during the 1850's between supporters and opponents of a proposal to allow slavery in the Territory of Kansas. Because of shootings like this one, which occurred in 1858, the territory became known as "Bleeding Kansas."

lation that ended slavery in the District of Columbia and provided funds for any freed slaves who wished to move to Haiti or Liberia. In June, Lincoln signed a bill that ended slavery in all federal territories.

By July 1862, Lincoln was ready to accept African Americans in the Union Army. In September, he issued a preliminary order to *emancipate* (free) the slaves. It declared that all slaves in areas or states in rebellion against the United States on Jan. 1, 1863, would be forever free. The order excluded areas still loyal to the Union, meaning that they might retain slaves. The order had no immediate effect in the Southern-controlled areas, but it meant that each Union victory brought the end of slavery closer. The final order was issued on Jan. 1, 1863, as the Emancipation Proclamation. African Americans referred to that day as the Day of Jubilee. Bells rang from the spires of most Northern black churches to celebrate the day.

Over 200,000 African Americans fought on the side of the Union. They were discriminated against in pay, assignments, and rank. Nevertheless, many of them contributed greatly to the war effort. Robert Smalls of South Carolina, a harbor pilot, was one of the first black heroes. In 1862, he sailed a Confederate ship, the *Planter,* out of Charleston Harbor and turned it over to the Union. Smalls then joined the Union Navy. In 1863, black regiments played an important role in the attack on Port Hudson, La. The fall of Port Hudson helped the Union gain control of the Mississippi River. Altogether, 23 blacks won the Medal of Honor, the nation's highest military award, for heroism during the Civil War.

The Confederate States did not decide to use blacks as soldiers until 1865, the last year of the war. About 40,000 black troops—nearly all of them Union troops—died during the war. In April 1865, the main Southern army surrendered. In December 1865, the adoption of the 13th Amendment to the U.S. Constitution officially ended slavery throughout the nation.

The first years of freedom. The period of rebuilding that followed the Civil War became known as Reconstruction. A major concern during Reconstruction was the condition of the approximately 4 million *freedmen* (freed slaves). Most of them had no homes, were desperately poor, and could not read and write.

To help the freed slaves and homeless whites, Congress established the Bureau of Refugees, Freedmen, and Abandoned Lands. The agency, better known as the Freedmen's Bureau, operated from 1865 until 1872. It issued food and supplies to blacks; set up more than 100 hospitals; resettled more than 30,000 people; and founded over 4,300 schools. Some of the schools developed into outstanding black institutions, such as Atlanta University (now Clark Atlanta University), Fisk University, Hampton Institute, and Howard University.

In spite of its achievements, the Freedmen's Bureau did not solve the serious economic problems of African Americans. Most of them continued to live in poverty. They also suffered from racist threats and violence and from laws restricting their civil rights. All these problems cast a deep shadow over their new freedom.

The legal restrictions on black civil rights arose in 1865 and 1866, when many Southern state governments passed laws that became known as the *black codes.* These laws were like the earlier slave codes. Some black codes prohibited blacks from owning land. Others established a nightly curfew for blacks. Some permitted states to jail blacks for being jobless.

The black codes shocked a powerful group of Northern congressmen called Radical Republicans. These senators and representatives won congressional approval of the Civil Rights Act of 1866. The act gave African Americans the rights and privileges of full citizenship. The 14th Amendment to the Constitution, adopted in 1868, further guaranteed the citizenship of blacks. However, most Southern whites resented the new status of blacks. The whites simply could not accept the idea of former slaves voting and holding office. As a result, attempts by Southern blacks to vote, run for public office, or enjoy other civil rights were met by increasing violence from whites in the South. In 1865 and 1866, about 5,000 Southern blacks were murdered. Forty-six blacks were killed when their schools and churches were burned in Memphis in May 1866. In July, 34 blacks were killed during a race riot in New Orleans.

Some law enforcement officers encouraged or participated in assaults on blacks. But lawless groups carried

African American troops made important contributions to the Union victory in the Civil War. Over 200,000 blacks served in segregated Northern units, such as the 2nd U.S. Colored Artillery, *above.*

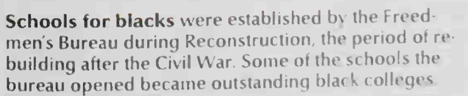
out most attacks. One of the largest, the Ku Klux Klan, was organized in 1865 or 1866 in Pulaski, Tenn. Bands of hooded Klansmen rode at night and beat and murdered many blacks and their white sympathizers. The Klan did much to deny blacks their civil and human rights throughout Reconstruction.

The federal government tried to maintain the rights of African Americans. In 1870 and 1871, Congress passed laws authorizing the use of federal troops to enforce the voting rights of blacks. These laws were known as the Enforcement Acts or the Ku Klux Klan Acts. In addition, President Ulysses S. Grant signed a proclamation demanding respect for the civil rights of all Americans.

Temporary gains. The policies of the Radical Republicans enabled African Americans to participate widely in the nation's political system for the first time. Congress provided for black men to become voters in the South and called for constitutional conventions to be held in the defeated states. Many blacks attended the conventions held in 1867 and 1868. They helped rewrite Southern state constitutions and other basic laws to replace the black codes drawn up by whites in 1865 and 1866. In the legislatures elected under the new constitutions, however, blacks had a majority of seats only in the lower house in South Carolina. Most of the chief legislative and executive positions were held by Northern white Republicans who had moved to the South and by their white Southern allies. Angry white Southerners called the Northerners *carpetbaggers* to suggest that they could carry everything they owned when they came South in a *carpetbag,* or suitcase.

African Americans elected to important posts during Reconstruction included U.S. Senators Hiram R. Revels and Blanche K. Bruce of Mississippi and U.S. Representatives Joseph H. Rainey of South Carolina and Jefferson Long of Georgia. Others were Oscar J. Dunn, lieutenant governor of Louisiana; Richard Gleaves and Alonzo J. Ransier, lieutenant governors of South Carolina; P. B. S. Pinchback, acting governor of Louisiana; Francis L. Cardozo, secretary of state and state treasurer of South Carolina; and Jonathan Jasper Wright, an associate justice of the South Carolina Supreme Court. Most of them had college educations.

By the early 1870's, Northern whites had lost interest in the Reconstruction policies of the Radical Republicans. They grew tired of hearing about the continual conflict between Southern blacks and whites. Most Northern whites wanted to put Reconstruction behind them and turn to other things. Federal troops sent to the South to protect blacks were gradually withdrawn. Southern whites who had stayed away from elections to protest black participation started voting again. White Democrats then began to regain control of the state governments from the blacks and their white Republican associates. In 1877, the last federal troops were withdrawn. By the end of that year, the Democrats held power in all the Southern state governments. For more details on the Reconstruction era, see **Reconstruction**.



The growth of discrimination

During the late 1800's, blacks in the South increasingly suffered from segregation, the loss of voting rights, and other forms of discrimination. Their condition reflected beliefs held by most Southern whites that whites were born superior to blacks with respect to intelligence, talents, and moral standards. In 1881, the Tennessee legislature passed a law that required railroad passengers to be separated by race. In 1890, Mississippi adopted several measures that in effect ended voting by African Americans. These measures included the passing of reading and writing tests and the payment of a poll tax before a person could vote.

Several decisions of the U.S. Supreme Court enabled the Southern States to establish "legal" segregation practices. In 1883, for example, the court declared the Civil Rights Act of 1875 to be unconstitutional. That act had guaranteed blacks the right to be admitted to any public place. In addition, the Civil Rights Act of 1866 and the 14th Amendment to the Constitution, ratified in 1868, had forbidden the states to deny equal rights to any person. But in 1896, the Supreme Court ruled in the case of *Plessy v. Ferguson* that a Louisiana law requiring the separation of black and white railroad passengers was constitutional. The court argued that segregation in itself did not represent inequality and that separate public facilities could be provided for the races as long as

the facilities were equal. This ruling, known as the "separate but equal doctrine," became the basis of Southern race relations. In practice, however, nearly all of the separate public facilities provided for blacks were far inferior to those provided for whites.

In spite of the increasing difficulties for African Americans, a number of them won distinction during the late 1800's. For example, Samuel Lowery started a school for blacks in Huntsville, Ala., in 1875 and won prizes at international fairs for silk made at the school. In 1883, Jan E. Matzeliger invented a revolutionary shoe-lasting machine that shaped the upper part of a shoe and fastened it to the sole. In 1887, Joe Clark and a group of other blacks founded Eatonville, Florida. It was the first African American settlement in the United States to be incorporated. Mary Church Terrell helped found the National Association of Colored Women in 1896 and advised government leaders on racial problems. Charles Waddell Chesnutt wrote *The Conjure Woman,* published in 1899. He became the first major African American novelist and short-story writer.

During the early 1900's, discrimination against Southern blacks became even more widespread. By 1907, every Southern state required racial segregation on trains and in churches, schools, hotels, restaurants, theaters, and other public places. The Southern States also adopted an election practice known as the *white primary.* The states banned blacks from voting in the Democratic Party's primary elections by calling them "private affairs." But the winners of the primary elections were certain of victory in the general elections because Republican and independent candidates got little support from whites and rarely ran for office. By 1910, every Southern state had taken away or begun to take away the right of African Americans to vote.

The Ku Klux Klan also attempted to keep blacks from voting through an increased use of threats, beatings, and killings. More than 3,000 blacks had been lynched during the late 1800's, and the Klan and members of similar groups lynched hundreds more throughout the South during the early 1900's.

African Americans had little opportunity to better themselves economically. Some laws prohibited them from teaching and from entering certain other businesses and professions. Large numbers of blacks had to take low-paying jobs as farm hands or servants for white employers. Many other blacks became sharecroppers or tenant farmers. They rented a small plot of land and paid the rent with money earned from the crops. They had to struggle to survive, and many ran up huge debts to their white landlords or the town merchants.

The rise of new black leaders. By the early 1900's, educator Booker T. Washington had become the most influential African American leader. Washington, a former slave, had been principal of Tuskegee Institute (now Tuskegee University) since 1881. He urged blacks to stop demanding political power and social equality and to concentrate on economic advancement. Washington especially encouraged blacks to practice thrift and respect hard labor. He asked whites to help blacks gain an education and make a decent living. Washington believed his program would lead to progress for blacks and would keep peace between the races.

Many African Americans agreed with Washington's ideas. But many others strongly rejected them. The chief opposition came from W. E. B. Du Bois, a sociologist and historian at Atlanta University. Du Bois' reputation rested on such works as *The Suppression of the African Slave-Trade to the United States of America, 1638-1870* (1896) and *The Souls of Black Folk* (1903).

Du Bois argued that Washington's approach would not achieve economic security for African Americans. Instead, Du Bois felt Washington's acceptance of segregation and the rest of his program would strengthen the beliefs that blacks were inferior and could be treated unequally. As evidence for their position, Du Bois and his supporters pointed to the continuing lynching of blacks and to the passage of additional segregation laws in the South. In 1905, Du Bois and other critics of Washington met in Niagara Falls, Canada, and organized a campaign to protest racial discrimination. Their campaign became known as the Niagara Movement.

Bitter hostility toward blacks erupted into several race riots during the early 1900's. Major riots broke out in Brownsville, Tex., and Atlanta, Ga., in 1906 and in Springfield, Ill., in 1908. The riots alarmed many white North-

erners as well as many blacks. In 1909, a number of white Northerners joined some of the blacks in the Niagara Movement to form the National Association for the Advancement of Colored People (NAACP). The NAACP vowed to fight for racial equality. The organization relied mainly on legal action, education, protests, and voter participation to pursue its goals.

The black migration to the North. The efforts of new black leaders and of the NAACP did little to end the discrimination, police brutality, and lynchings suffered by Southern blacks during the early 1900's. In addition, Southern farmers had great crop losses because of floods and insect pests. All these problems persuaded many Southern blacks to move to the North.

During World War I (1914-1918), hundreds of thousands of Southern blacks migrated to the North to seek jobs in defense plants and other factories. The National Urban League, founded in New York City in 1910, helped the newcomers adjust to city life. Over 360,000 African Americans served in the armed forces during World War I. They were put in all-black military units.

Between 1910 and 1930, about 1 million Southern blacks moved to the North. Most of them quickly discovered that the North did not offer solutions to their problems. They lacked the skills and education needed for the jobs they sought. Many of them had to become laborers or servants and thus do the same kinds of work they had done in the South. Others could find no work at all. Numerous blacks were forced to live crowded together in cheap, unsanitary, run-down housing. Large all-black slums developed in big cities throughout the North. The segregated housing promoted segregated schooling. Poverty, crime, and despair plagued the black communities, which became known as *ghettos*.

After World War I, race relations grew increasingly tense in the Northern cities. The hostility partly reflected the growing competition for jobs and housing between blacks and whites. In addition, many African American veterans, after fighting for democracy, returned home with expectations of justice and equality. The mounting tension helped the Ku Klux Klan recruit thousands of members in the North. In the summer of 1918, 10 people were killed and 60 were injured in racial disturbances in Chester and Philadelphia, Pa. A series of riots erupted in the summer of 1919. By the end of the year, 25 race riots had broken out across the country. At least 100 people died and many more were injured in the riots.

The Garvey movement offered new hope for many African Americans deeply disturbed by the race riots of 1918 and 1919 and the economic and social injustice they encountered. The movement had begun when Marcus Garvey founded the Universal Negro Improvement Association in Jamaica in 1914. In 1917, Garvey brought the movement to Harlem, a black community in New York City. By the mid-1920's, he had established more than 700 branches of the association in 38 states.

Garvey tried to develop racial pride among blacks. But he doubted that their life in the United States would ever be much improved. As a result, Garvey urged the establishment of a new homeland in Africa for dissatisfied black Americans. His plans collapsed, however, when he was sent to prison in 1925 after having been convicted of using the mails to commit fraud.

The Harlem Renaissance and other achievements. The Harlem Renaissance was an outpouring of African American literature chiefly in Harlem in the early 1900's, particularly in the 1920's. It demonstrated that some blacks had acquired talents within American society which whites as well as blacks could appreciate. The writers drew their themes from the experiences of blacks in the Northern cities and the rural South. The best-known writers included James Weldon Johnson, Langston Hughes, Nella Larsen, Claude McKay, Countee Cullen, Jessie Redmon Fauset, and Jean Toomer.

African American musicians also gained fame among whites as well as blacks during the early 1920's. A black bandleader named W. C. Handy, who had composed "St. Louis Blues" in 1914, became known as the father of the blues. Jazz grew out of black folk blues and ballads. African American bandleaders Louis Armstrong and Duke Ellington became the country's leading jazz musicians.

Another noted black of the early 1900's was the great agricultural researcher George Washington Carver. Carver created hundreds of products from peanuts, sweet potatoes, and other plants and revolutionized Southern agriculture. Other famous African Americans of the early

Duke Ellington, playing the piano in this scene from the movie *Cabin in the Sky* (1943), became one of the greatest jazz musicians.

1900's included labor leader A. Philip Randolph, journalist Ida Wells-Barnett, singer Paul Robeson, dancer Bill Robinson, U.S. Representative Oscar DePriest of Illinois, runner Jesse Owens, and heavyweight boxing champions Jack Johnson and Joe Louis.

The Great Depression. In October 1929, a sudden, sharp drop in the value of stocks in the United States marked the beginning of a worldwide business slump known as the Great Depression. The depression brought hard times for most Americans, but especially for blacks. Blacks became the chief victims of job discrimination. They adopted the slogan "Last Hired and First Fired" to express their situation.

To help ease the poverty in the ghettos, African Americans organized cooperative groups. These groups included the Colored Merchants Association in New York City and "Jobs for Negroes" organizations in St. Louis, Chicago, Cleveland, and New York City. The groups bought food and other goods in large volume to get the lowest prices. They boycotted stores that had mostly black customers but few, if any, black workers.

Most African Americans felt that President Herbert Hoover, a Republican, had done little to try to end the Depression. In the elections of 1932, some black voters deserted their traditional loyalty to the Republican Party. They no longer saw it as the party of Abraham Lincoln the emancipator but of Hoover and the Depression. In 1936, for the first time, most African Americans supported the Democratic Party candidate for President, Franklin D. Roosevelt, and helped him win reelection.

Roosevelt called his program the New Deal. It included measures of reform, relief, and recovery and benefited many blacks. A group of blacks advised Roosevelt on the problems of African Americans. This group, called the Black Cabinet, included William H. Hastie and Mary McLeod Bethune. Hastie served as assistant solicitor in the Department of the Interior, as a U.S. district court judge in the Virgin Islands, and as a civilian aide to the secretary of war. Bethune, founder of Bethune-Cookman College, directed the black affairs division of a federal agency called the National Youth Administration. As a result of the New Deal, African Americans developed a strong loyalty to the Democratic Party.

African Americans deeply admired President Roosevelt's wife, Eleanor, for her stand in an incident in 1939 involving the great concert singer Marian Anderson. The Daughters of the American Revolution (DAR), a patriotic organization, denied the singer permission to perform at Constitution Hall in Washington, D.C., because she was black. Eleanor Roosevelt then resigned from the DAR and helped arrange for Anderson to sing, instead, at the Lincoln Memorial on Easter Sunday. Over 75,000 blacks and whites attended the concert.

During the early 1940's, the NAACP began to step up its legal campaign against racial discrimination. The campaign achieved a number of important victories, including several favorable rulings by the U.S. Supreme Court. In 1941, for example, the court ruled that separate facilities for white and black railroad passengers must be significantly equal. In 1944, the court declared that the white primary, which excluded blacks from voting in the only meaningful elections in the South, was unconstitutional.

Besides taking legal action, African Americans used new tactics to attack segregation in public places. In 1943, for example, the Congress of Racial Equality (CORE) launched a *sit-in* at a Chicago restaurant. In this protest, blacks sat in places reserved for white people.

World War II (1939-1945) opened up new economic opportunities for African Americans. Like World War I, it led to expanding defense-related industries and encouraged many rural Southern blacks to seek jobs in Northern industrial cities. During the 1940's, about a million Southern blacks moved to the North. Discrimination again prevented many of them from getting work. In 1941, blacks led by A. Philip Randolph of the Brotherhood of Sleeping Car Porters threatened to march in Washington, D.C., to protest job discrimination. President Roosevelt then issued an executive order forbidding racial discrimination in defense industries.

Nearly 1 million African Americans served in the U.S. armed services during World War II, mostly in segregated units. In 1940, Benjamin O. Davis became the first black brigadier general in the U.S. Army. His son, Benjamin O. Davis, Jr., later became the first black lieutenant general in the Air Force. Desegregation of the armed

forces began on a trial basis during the war. It became a permanent policy in 1948.

The civil rights movement

The beginning. After World War II, three major factors encouraged the beginning of a new movement for civil rights. First, many African Americans had served with honor in the war. Black leaders pointed to the records of these veterans to show the injustice of racial discrimination against patriots. Second, African Americans in the urban North had made economic gains, increased their education, and registered to vote. Third, the NAACP had attracted many new members and received increased financial support from whites and blacks. It also included a new group of bright young lawyers.

Rulings by the U.S. Supreme Court during the 1940's and 1950's brought major victories for African Americans. In several decisions between 1948 and 1951, the court ruled that separate higher education facilities for blacks must be equal to those for whites. Largely because of federal court rulings, laws permitting racial discrimination in housing and recreation also began to be struck down. Many of these rulings came in cases brought by the NAACP. An increasing number of blacks began to move into all-white areas of Northern cities. Many whites then moved out of the cities to suburbs.

The NAACP and the NAACP Legal Defense and Educational Fund won a historic victory in 1954. That year, the U.S. Supreme Court ruled in the case of *Brown v. Board of Education of Topeka* that segregation in the public schools was in itself unequal and thus unconstitutional. The suit had been filed because the school board had not allowed a black student named Linda Brown to attend an all-white school near her home. The court's decision rejected the separate but equal ruling of 1896 and inspired African Americans to strike out against other discrimination, particularly in public places.

Rosa Parks, a seamstress and civil rights activist in Montgomery, Alabama, became a symbol of African Americans' bold new action to attain their civil rights. In 1955, she was arrested for disobeying a city law that required blacks to give up their seats when white people wished to sit in their seats or in the same row. Montgomery's blacks protested her arrest by refusing to ride the buses. Their protest lasted 382 days, ending when the city abolished the bus law. The boycott became the first organized mass protest by blacks in Southern history. It also focused national attention on its leader, Martin Luther King, Jr., a Montgomery Baptist minister.

Many Southern communities acted slowly in desegregating their public schools. Governor Orval E. Faubus of Arkansas symbolized Southern resistance. In 1957, he defied a federal court order to integrate Little Rock Central High School. Faubus sent the Arkansas National Guard to prevent black students from entering the school, but President Dwight D. Eisenhower used federal troops to enforce the court order.

The growing movement. In 1957, King and other black Southern clergymen formed the Southern Christian Leadership Conference (SCLC) to coordinate the work of civil rights groups. King urged African Americans to use peaceful means to achieve their goals. In 1960, a group of black and white college students organized the Student Nonviolent Coordinating Committee (SNCC) to help in the civil rights movement. They joined with young people from the SCLC, CORE, and the NAACP in staging sit-ins, boycotts, marches, and *freedom rides* (bus rides to test the enforcement of desegregation in interstate transportation). During the early 1960's, the combined efforts of the civil rights groups ended discrimination in many public places, including restaurants, hotels, theaters, and cemeteries.

Numerous cities and towns remained unaffected by the civil rights movement. African American leaders therefore felt the United States needed a clear, strong federal policy that would erase all remaining discrimination in public places. To attract national attention to that need, King and such other leaders as A. Philip Randolph, Roy Wilkins of the NAACP, James L. Farmer of CORE, and Whitney M. Young, Jr., of the Urban League organized a march in Washington, D.C., in August 1963. More than 200,000 people, including many whites, took part in what was called the March on Washington.

A high point of the March on Washington was a stirring speech by King. King told the crowd that he had a dream that one day all Americans would enjoy equality

United States troops enforced a federal court order to integrate Little Rock Central High School in Arkansas in 1957.

and justice. Afterward, President John F. Kennedy proposed strong laws to protect the civil rights of all U.S. citizens. But many people, particularly Southerners, opposed such legislation.

Kennedy was assassinated in November 1963, and Vice President Lyndon B. Johnson became President. Johnson persuaded Congress to pass Kennedy's proposed laws in the Civil Rights Act of 1964. This act prohibited racial discrimination in public places and called for equal opportunity in employment and education. King won the 1964 Nobel Peace Prize for leading nonviolent demonstrations for civil rights.

African American celebrities not directly involved with civil rights groups also contributed to the growing civil rights movement. Author James Baldwin criticized white Americans for their prejudice against blacks. Other noted African Americans who promoted civil rights causes included gospel singer Mahalia Jackson, dancer Katherine Dunham, artist Charles White, singer Harry Belafonte, and comedian Dick Gregory.

Political gains. In the South, many elected officials and police officers refused to enforce court rulings and federal laws that gave blacks equality. In some cases, this opposition extended to the right to vote.

In 1965, a major dispute over voting rights broke out in Selma, Alabama. King had gone there in January to assist African Americans seeking the right to vote. He was joined by many blacks and whites from throughout the country. In the next two months, at least three people were killed and hundreds were beaten as opposition to King's efforts increased. But authorities continued to deny blacks their voting rights. In late March, King led about 30,000 people, guarded by federal troops, from Selma to the State Capitol in Montgomery. There, he demanded that African Americans be given the right to vote without unjust restrictions.

Largely as a result of the activities in Selma, Congress passed the Voting Rights Act of 1965. The act banned the use of a poll tax as a requirement to vote and forbade major changes in Southern voting laws without approval of the Department of Justice. In addition, it provided for federal officials to supervise voter registration wherever the right to vote had been unjustly denied. The act gave the vote to thousands of Southern blacks who had never voted and led to a huge increase in the number of black elected officials.

African Americans began to take an increasingly important role in the national government during the mid-1900's. In 1950, U.S. diplomat Ralph J. Bunche became the first black person to win the Nobel Peace Prize. In 1966, Robert C. Weaver became the first black Cabinet member as secretary of housing and urban development. In 1967, Thurgood Marshall became the first black justice on the Supreme Court. In 1969, Shirley Chisholm of New York became the first black woman to serve in the U.S. House of Representatives.

Economic and social progress. In 1965, President Johnson declared that it was not enough simply to end *de jure* segregation—that is, separation of the races by law. It was also necessary to eliminate *de facto* segregation—that is, racial separation in fact and based largely on custom. Johnson called for programs of "affirmative action" that would offer blacks equal opportunity with whites in areas where discrimination had a long history and still existed. Many businesses and schools then began to adopt affirmative action programs. These programs, some of which were ordered by the federal government, gave hundreds of thousands of blacks new economic and educational opportunities.

The new economic opportunities enabled many African Americans to increase their incomes significantly during the mid-1900's. This development, in turn, greatly expanded the black middle class.

Racial barriers fell in several professional sports and in the arts during the mid-1900's. In 1947, Jackie Robinson of the Brooklyn Dodgers became the first black player in modern major league baseball. He had an outstanding career and became a national hero. Other black sports heroes of the mid-1900's included Willie Mays, Henry Aaron, and Frank Robinson in baseball; Jim Brown and Gale Sayers in football; and Oscar Robertson, Bill Russell, and Wilt Chamberlain in basketball. In 1966, Russell became the first black head coach in major league professional sports. He was named coach of the Boston Celtics of the National Basketball Association.

In the arts, Gwendolyn Brooks became the first Afri-

can American to win a Pulitzer Prize. She received the award in 1950 for a collection of poems titled *Annie Allen.* In 1955, Marian Anderson became the first black to sing a leading role with the Metropolitan Opera in New York City. In 1958, Alvin Ailey formed one of the finest dance companies in the United States. Sidney Poitier won the 1963 Academy Award for best actor for his work in *Lilies of the Field.*

Unrest in the cities. Since the start of the civil rights movement, various court decisions, laws, and protests had clearly removed the great legal injustices long suffered by African Americans. But many blacks continued to be discriminated against in jobs, law enforcement, and housing. They saw little change in the long-held racist attitudes of numerous white Americans.

During the 1960's, unrest among ghetto blacks exploded into a series of riots that shook the nation. The first riot occurred in Harlem in the summer of 1964. In August 1965, 34 people died and almost 900 were injured in an outburst in the black ghetto of Watts in Los Angeles. During the next two summers, major riots erupted in numerous cities across the nation.

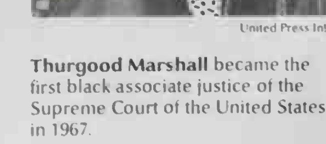
The race riots puzzled many people because they came at a time when African Americans had made tremendous gains in the campaign for full freedom. In 1967, President Johnson established a commission headed by Governor Otto Kerner of Illinois to study the causes of the outbreaks. In its March 1968 report, the Kerner Commission put much of the blame on racial prejudice of whites. It stated that the average black American was still poorly housed, clothed, paid, and educated and still often suffered from segregation, police abuse, and other forms of discrimination. The commission recommended vast programs to improve ghetto conditions and called for greater changes in the racial attitudes of white Americans.

Less than a month after the Kerner Commission report was issued, race riots broke out in at least 100 black communities across the nation. The rioting followed the assassination of Martin Luther King, Jr., on April 4 in Memphis, Tenn. James Earl Ray, a white drifter, was convicted of the crime and sentenced to 99 years in prison. King's murder helped President Johnson persuade Congress to approve the Civil Rights Act of 1968. This law, also known in part as the Fair Housing Act of 1968, prohibited racial discrimination in the sale and rental of most of the housing in the nation.

Black militancy. During the height of the civil rights movement, some blacks had charged it was almost impossible to change white racial attitudes. They saw the movement as meaningless and urged blacks to live apart from whites and, in some cases, to use violence to preserve their rights. Groups promoting these ideas included the Black Muslims, the Black Panthers, and members of the Black Power Movement.

The Black Muslims had been led since 1934 by Elijah Muhammad, who called whites "devils." He also criticized racial integration and urged formation of an all-black nation within the United States. But the most eloquent spokesman for the Black Muslims during the 1950's and 1960's was Malcolm X. Malcolm wanted to unite black people throughout the world. He was assassinated in 1965 after forming a new organization to pursue his goal. Three black men, at least two of whom were Black Muslims, were convicted of the murder.

The Black Panther Party was founded in 1966. Its two main founders, Huey P. Newton and Bobby Seale, had been inspired by Malcolm X. At first, the party favored violent revolution as the only way to end police actions that many blacks considered brutal and to provide opportunities for blacks in jobs and other areas. The Panthers had many clashes with police and others. Later, the party became less militant and worked to achieve full employment for blacks and other peaceful goals.



The Black Power Movement developed in 1966 after James H. Meredith, the first African American to attend the University of Mississippi, was shot during a march. The shooting and other racial violence made Stokely Carmichael, H. Rap Brown, and other members of the Student Nonviolent Coordinating Committee doubt the sincerity of white support for black rights.

Carmichael and other African Americans called for a campaign to achieve "Black Power." They urged blacks to gain political and economic control of their own communities and to reject the values of whites and form their own standards. They also stressed that "black is

beautiful" and suggested that black Americans no longer refer to themselves as *Negroes* or *colored people* but as *blacks, African Americans,* or *Afro-Americans.*

Developments since 1970

Achievements since the 1970's include great progress in education and politics. Many blacks have won recognition in such fields as sports and the arts.

Education gains have been significant. From 1970 to the early 1990's, college enrollments among African Americans rose from about 600,000 to about 1,300,000. This gain resulted in part from affirmative action programs by predominantly white colleges and universities. By the early 1990's, about 13 percent of all blacks 25 years of age or older had completed college. About three-fourths of that group had finished high school.

A black studies movement emerged on college campuses throughout the nation during the 1970's and drew increasing attention to the heritage of African Americans. In addition, black musical and theater groups and African American museums were established in almost every U.S. city with a fairly large black population.

Business. The number of black-owned businesses in the United States increased from about 190,000 to about 620,000 between 1970 and the mid-1990's. About 95 percent of these companies were small, one-owner firms.

Politics. The Voting Rights Act of 1965 led to the removal of restrictions on voting in most places. As a result, African Americans were able to help elect a greater number of blacks to public offices. In 1973, Thomas Bradley was elected the first black mayor of Los Angeles. That same year, Maynard H. Jackson was elected the first black mayor of a major Southern city, Atlanta, Georgia. In 1983, Harold Washington became the first black mayor of Chicago. David N. Dinkins was elected the first black mayor of New York City in 1989. That same year, L. Douglas Wilder became the first black to be elected governor of a U.S. state when he was elected governor of Virginia. In 1991, Sharon Pratt Dixon became the first black woman mayor of a large American city. She was elected mayor of Washington, D.C. Later that year, she married and changed her name to Sharon Pratt Kelly. In 1992, Carol Moseley-Braun became the first black woman to win election to the United States Senate.

African Americans gained considerable influence in the Administration of Jimmy Carter, who was president of the United States from 1977 to 1981. Under him, Andrew Young became the first black U.S. ambassador to the United Nations (UN). Carter named Patricia Roberts Harris secretary of housing and urban development. She was the first black woman to hold a Cabinet post.

Sports. Many African Americans have become famous sports figures. Black sports heroes include football players Walter Payton and Jerry Rice; basketball players Kareem Abdul-Jabbar, Magic Johnson, Julius Erving, and Michael Jordan; baseball stars Reggie Jackson, Tony Gwynn, and Frank Thomas; boxing champion Muhammad Ali, and track stars Carl Lewis, Florence Griffith Joyner, and Jackie Joyner-Kersee. Frank Robinson became the first black manager of a major league baseball team when he was named manager of the Cleveland Indians in 1974. In 1989, Bill White became the first black to head a major U.S. sports league when he was named president of baseball's National League. In 1995, Lenny Wilkens, head coach of the Atlanta Hawks, set a National Basketball Association record for career regular-season coaching victories with 939. In 1997, Tiger Woods became the first golfer with African American ancestry to win the Masters Tournament.

The arts. African Americans won recognition in all major art forms during the late 1900's and early 2000's. Leading writers included Maya Angelou, who received praise for her autobiography and her poetry. Alice Walker won a Pulitzer Prize in 1983 for her novel *The Color Purple.* Rita Dove served as poet laureate of the United States from 1993 to 1995. Toni Morrison, whose novel *Beloved* earned a Pulitzer Prize in 1988, received the Nobel Prize for literature in 1993. Plays by August Wilson won the Pulitzer Prize in 1987 and 1990. George C. Wolfe emerged as an outstanding director of plays.

In motion pictures, African American stars included Halle Berry, Morgan Freeman, Whoopi Goldberg, Eddie Murphy, and Denzel Washington. Filmmaker Spike Lee won praise for *Do the Right Thing* (1989) and *Malcolm X* (1992), as did filmmaker John Singleton for *Boyz N the Hood* (1991). Many blacks starred on television. "The

Toni Morrison received the Nobel Prize for literature in Stockholm, Sweden, in 1993. A novelist, she had won a Pulitzer Prize for her novel *Beloved* in 1988.

Cosby Show," featuring Bill Cosby, was a top-rated TV program in the United States from 1984 to 1992.

In music, opera singers Kathleen Battle and Jessye Norman became internationally recognized. Celebrated jazz musicians included Geri Allen, Roy Hargrove, Christian McBride, and Wynton Marsalis. Singer Michael Jackson became a superstar in popular music. His album *Thriller* (1982) sold over 45 million copies—more than any other album in history. African American performers used musical essays in verse called *rap music* to describe inner-city life. Leading "rappers" included Ice-T, Public Enemy, Run-DMC, and Queen Latifah. In 1996, George Walker became the first African American composer to win the Pulitzer Prize for music. He won for a work he wrote for voice and orchestra.

Other achievements. In 1983, Guion S. Bluford, Jr., became the first black U.S. astronaut to go into space. Mae C. Jemison became the first African American woman astronaut to do so in 1992. United States Army General Colin L. Powell was named the first black chairman of the Joint Chiefs of Staff in 1989. In 2001, Powell became the first African American secretary of state.

Disappointments and controversy. Several developments that began in the late 1970's have lessened the hopes of many African Americans for continued economic and social progress. For example, Supreme Court decisions from the 1970's to the 1990's sharply limited the scope of affirmative action programs. In 1978, the court ruled that racial quotas could not be used in admitting students to colleges and universities. In 1995, it ruled that federal programs requiring preferences for certain individuals based on their race are unconstitutional unless preferences are designed to make up for specific instances of past discrimination. This meant that affirmative action could no longer be used to counteract racial discrimination by society as a whole. In 1989, the court had made a similar decision regarding state and local affirmative action programs.

The 1995 ruling was supported by Supreme Court Justice Clarence Thomas, an African American who replaced Thurgood Marshall on the court when Marshall retired in 1991. Thomas had long been an outspoken opponent of affirmative action. He based his opposition on the principle that the government may not treat individuals differently based on their race. Many other blacks, however, continued to believe that broad affirmative action programs were needed to help minorities overcome past discrimination and eventually compete on an equal basis with whites.

In 1989, a study by the National Research Council indicated that the standard of living for blacks continued to lag far behind that for whites. The study showed that in 1984, the average income for blacks was only 57 percent of the average for whites. This percentage was the same as in 1971. The study also indicated that the difference in unemployment rates for blacks and whites had widened since the early 1970's. In the late 1980's, the rate for blacks was about $2\frac{1}{2}$ times that for whites. The study also showed that since the 1960's, there had been almost no progress in housing integration.

By 2000, the income gap between blacks and whites had narrowed somewhat. The average income for blacks in 2000 was 64 percent of that for whites. However, about 22 percent of black families still had incomes below the government's official poverty line, and the jobless rate for blacks was $2\frac{1}{4}$ times that for whites.

In 1991, Rodney G. King, a black motorist, was stopped after a pursuit and beaten by four white police officers in Los Angeles. As a result of the incident, the officers faced criminal charges, including assault. Although the beating was recorded on videotape, a jury declared three officers not guilty of all charges in 1992. One officer was acquitted of all charges except one, on which the jury was indecisive. This charge was later dropped. Many blacks felt the trial proved the U.S. court system treated blacks unfairly. The verdict sparked rioting in Los Angeles and other U.S. cities. Fifty-three people died and about 2,400 were injured in the Los Angeles riots. Later that year, all four officers were indicted under federal laws for violating King's civil rights. Two of the officers were convicted in 1993.

Developments in education. In the 1980's and 1990's, courses of study based on an approach called Afrocentrism gained popularity. These programs aim to encourage awareness of African culture and history and pride in the richness of African heritage. Most of the programs also emphasize past and present accomplishments of black people. Supporters of Afrocentrism believe the approach builds the self-esteem of African American children and improves their success in school. Opponents say that some Afrocentric teaching materials are based on faulty scholarship.

Another trend is the use of a variation of English known as black English, Ebonics, or African American vernacular English. Characteristics of black English include extensive use of the verb *to be* and omissions of verbs. Some language experts think that some patterns of Ebonics are based on west African languages.

The use of black English in schools gained national attention in 1996 and 1997 when the Oakland, California, school district adopted and later dropped a plan to recognize it as a language. Some schools employ it as an aid in the teaching of standard English. Proponents of black English say that African American students learn better when it is used in this manner. Opponents of black English claim that it could discourage students from learning standard English.

Black politics today. Many African American leaders today stress the use of political means to solve the problems of blacks. They urge more African Americans to vote and to run for public office.

In 1984, Jesse L. Jackson, a black civil rights leader and Baptist minister, waged a strong campaign to register new black voters and win the Democratic presidential nomination. Jackson's bid failed, but he became a hero to most African Americans. He made an even stronger run for the nomination in 1988. Although his bid again failed, Jackson gained the support of more convention delegates than any other candidate except Michael S. Dukakis, who won the nomination.

In the early 2000's, blacks held about 8,900 of some 500,000 elective offices in the nation. Thirty-eight served in the U.S. House of Representatives, including two nonvoting delegates. None served in the Senate.

Many African Americans feared that Supreme Court rulings would reduce the number of blacks serving in the House. In these rulings, the court declared that race could not be used as the main factor in drawing the

boundaries of congressional districts. An increasing number of states had created black-majority districts by redrawing such boundaries. Many of the new districts had elected blacks to the House.

In the 1990's, many African Americans focused on building up black communities, particularly in cities. Many reformers supported self-help programs to deal with crime, drug abuse, poverty, and substandard education. In 1995, hundreds of thousands of black men marched in Washington, D.C., to declare their determination to improve conditions in black communities. The event, called the Million Man March, was organized chiefly by Louis Farrakhan, leader of the Nation of Islam, a Black Muslim group. The Million Woman March, a similar event, drew several hundred thousand black women to Philadelphia in 1997. It was organized chiefly by Phile Chionesu and Asia Coney. In 2000, Farrakhan led another march in Washington, the Million Family March, with a focus on family unity. Alton Hornsby, Jr.

African hunting dog is a wild dog known for its large, round ears and sparse, tricolored coat. This coat consists of irregular patches of black, brown, and white fur. The dog also has long legs, a deep chest, and powerful jaws and teeth. An adult weighs from 45 to 67

© Len Rue, Jr., Animals Animals

The African hunting dog is an endangered species.

pounds (20 to 30 kilograms) and stands 24 to 30 inches (60 to 75 centimeters) tall at the shoulders.

African hunting dogs usually live in packs of about 10 to 40 animals. A dominant male and female, who form a breeding pair, lead each pack. The dominant female gives birth in a den to a litter of 6 to 16 pups. The pack assists in grooming, feeding, and protecting the litter. African hunting dogs usually hunt gazelles and antelope, but they may also kill zebras and gnus. They hunt during the day in packs, often surrounding their victim and chasing it until it is exhausted.

These dogs once roamed in large numbers throughout much of Africa. Today, however, they are an endangered species. Only a few thousand dogs remain, mostly on wildlife parks and reserves in eastern and southern Africa. Increasing human population, disease, competition from hyenas, and other factors have greatly reduced the dog's population. Duane A. Schlitter

Scientific classification. The African hunting dog belongs to the dog family, Canidae. Its scientific name is *Lycaon pictus.*

African lion hound. See Rhodesian ridgeback.

African Methodist Episcopal Church (A.M.E.) is one of the largest Methodist denominations in the United States. It was founded by African American Methodists who withdrew in 1787 from St. George Methodist Episcopal Church in Philadelphia to protest segregation. Blacks then made up a large percentage of the Methodists in the United States. Two free blacks, Richard Allen and Absalom Jones, led the withdrawal. The church name was chosen to indicate it was formed by people of African descent. But the church has never had a policy of discrimination and has members of all races.

Twenty bishops serve the church in the 50 states, Canada, 14 African countries, the Caribbean, and South America. The church operates six senior colleges and two junior colleges. Critically reviewed by the A.M.E. Church

See also Allen, Richard.

African Methodist Episcopal Zion Church (A.M.E. Zion) is a large Methodist denomination in the United States. It was formed in 1796 by a group of African Americans who withdrew from the John Street Methodist Episcopal Church in New York City. The John Street church had both white and black members. Many leaders of the abolitionist movement of the 1800's were members of the A.M.E. Zion Church. They included Harriet Tubman, Sojourner Truth, and Frederick Douglass.

A general conference is the church's supreme administrative body. Between meetings of the conference, the church is administered by the Board of Bishops. The denomination operates Livingstone College in Salisbury, North Carolina, and two junior colleges. Its missionaries serve in North and South America, Africa, and the Caribbean region. Critically reviewed by the A.M.E. Zion Church

African National Congress (ANC) is a political party in South Africa. It played a major role in winning political and civil rights for the country's blacks, who make up about three-fourths of the population. Until 1994, South African law denied them the right to vote in national elections and to participate in the national government. Most ANC members are black, though whites, Asians, and people of mixed ancestry are also members.

The ANC was founded in 1912 by South African blacks to defend their political rights. In 1948, the South African government started a policy of rigid racial segregation called *apartheid.* Young ANC members, led by lawyer Nelson Mandela, began to resist the government, chiefly through civil disobedience. In 1960, the government outlawed the ANC. The ANC then began a policy of violent resistance to apartheid. Numerous members, including Mandela, were imprisoned. Some were killed or exiled. Many nations opposed apartheid, and South Africa grew isolated in the world community.

In February 1990, South Africa legalized the ANC and released Mandela and other ANC leaders from prison. In May 1990, the ANC and the government began talks aimed at giving nonwhites the same rights to vote and participate in government that whites had. In August, the ANC declared it would abandon the use of violence. In 1991, the government repealed the last of the laws that formed the legal basis of apartheid.

In 1994, South Africa held its first national elections in which blacks were allowed to vote. The ANC won a majority of seats in the new National Assembly. The Assembly, in turn, elected Mandela president of South Africa. In elections held in 1999, the ANC again won a majority of seats in the Assembly, which then elected ANC leader Thabo Mbeki president of South Africa. Mandela had stepped down as head of the ANC in 1997 and had retired as South Africa's president in 1999. Bruce Fetter

African Union (AU) is an organization that works to achieve greater political, social, and economic cooperation among African governments and peoples. The AU consists of 52 independent countries and a government-in-exile. The AU replaced a previous group, the Organization of African Unity (OAU), in 2002 (see Organization of African Unity). The structure of the AU is to be similar to that of the European Union (see European Union).

Members of the African Union

Algeria	Libya
Angola	Madagascar
Benin	Malawi
Botswana	Mali
Burkina Faso	Mauritania
Burundi	Mauritius
Cameroon	Mozambique
Cape Verde	Namibia
Central African Republic	Niger
Chad	Nigeria
Comoros	Rwanda
Congo (Brazzaville)	Saharawi Arab Democratic Republic*
Congo (Kinshasa)	São Tomé and Príncipe
Côte d'Ivoire	Senegal
Djibouti	Seychelles
Egypt	Sierra Leone
Equatorial Guinea	Somalia
Eritrea	South Africa
Ethiopia	Sudan
Gabon	Swaziland
Gambia	Tanzania
Ghana	Togo
Guinea	Tunisia
Guinea-Bissau	Uganda
Kenya	Zambia
Lesotho	Zimbabwe
Liberia	

*The Saharawi Arab Democratic Republic is a government-in-exile that was formed by the Polisario Front, an organization seeking independence for the northwest African territory of Western Sahara.

OAU leaders signed the Constitutive Act of the African Union in 2000. The act entered into force in 2001, and the AU officially replaced the OAU on July 9, 2002. The act outlines several AU objectives. These include working toward further political and economic integration of Africa; defending the independence of member states; promoting peace, cooperation, security, and stability in Africa; promoting democratic principles and human rights; raising the living standards of Africa's people; encouraging scientific and technological research; and working to eradicate diseases and promote good health. The act calls for participation of African peoples in AU activities. It also says the AU will reject unconstitutional changes of government in African countries.

The AU's supreme body is the Assembly of the Union, which consists of the member countries' heads of state and heads of government or their recognized representatives. It will meet at least once a year. An Executive Council, made up of ministers of foreign affairs and other authorities representing the member states, will make administrative decisions on behalf of the Assembly. The AU has a peace and security council that is modeled after the United Nations (UN) Security Council. The AU also will include a Pan-African Parliament, a Court of Justice, financial institutions, and a number of other administrative bodies. The headquarters of the AU are in Addis Ababa, Ethiopia. Mammo Muchie

African violet, also called *Saintpaulia,* is a tropical plant with beautiful flowers and heart-shaped, fuzzy leaves. It is not a true violet. A native of Africa, it is widely cultivated as a house plant. It thrives in moderate temperatures and soil rich in *humus* (decayed matter). The African violet grows from 3 to 5 inches (8 to 13 centimeters) tall.

© Derek Fell

African violet

The flowers, up to 1 inch (2.5 centimeters) across, grow in clusters of three or more on slender stalks. They range in color from white to pink to violet. The name *Saintpaulia* comes from Baron Walter von Saint Paul-Illaire, a German nobleman who discovered the plant in 1892.

Thomas B. Croat

Scientific classification. African violet belongs to the gesneria family, Gesneriaceae. It is classified as *Saintpaulia ionantha.*

Afrikaners, *af ruh KAH nuhrz,* are people of Dutch, German, or French ancestry who live in South Africa. Most Afrikaners are of Dutch descent. The first Afrikaners were colonists sent to South Africa in 1652 by the Dutch East India Company, a trading firm. Many of the colonists became farmers. Afrikaners are also called *Boers* (pronounced *bawrz*). *Boer* is a Dutch term meaning *farmer.* Afrikaners speak the *Afrikaans* language, which is derived from Dutch.

The British occupied the colony the Afrikaners founded in 1795, but withdrew in 1802. They seized the land again in 1806 and held it. In 1836, some Afrikaners left the colony to gain freedom from British rule. They moved northeast into lands that became known as Natal, the Orange Free State, and the Transvaal. On this "Great Trek," the Afrikaners faced grave dangers and hardships. Later, they lost to the British in the Anglo-Boer War of 1899-1902. Today, Afrikaners outnumber people of British descent in South Africa. T. O. Beidelman

AFS Intercultural Programs is a nonprofit organization that promotes worldwide learning and living experiences for secondary school students, young adults, and families. It was formerly known as the American Field Service. AFS is active in about 70 countries. Most AFS programs involve the international exchange of students 16 to 18 years old. The student lives with a family in another country for a summer or for a year and attends a local school. AFS also runs programs for young professionals in education, journalism, economics, banking, law, agriculture, and language.

The American Field Service was founded in 1914 as a volunteer ambulance corps during World War I. In 1947, it established the exchange program for students. AFS adopted its present name in 1987. It has headquarters in New York City. Critically reviewed by AFS Intercultural Programs

Agamemnon, *AG uh MEHM nahn,* in Greek mythology, led the Greek army that conquered Troy in the Trojan War. Agamemnon was the king of Mycenae (or Argos). He married the princess Clytemnestra. Their children included Electra, Iphigenia, and Orestes.

Agamemnon assembled the Greek forces at Aulis before sailing for Troy. But the goddess Artemis refused to send favorable winds because Agamemnon had offended her. At Artemis's command, Agamemnon sacrificed his daughter Iphigenia so that the army could sail for Troy. One version tells that Iphigenia died in the sacrifice. Another tells that Artemis rescued her.

In the last year of the Trojan War, Agamemnon angered the god Apollo because he refused to return the captured maiden Chryseis to her father, a priest of Apollo. As punishment, Apollo sent a plague to afflict the Greek army. Agamemnon then returned Chryseis but, in exchange, he demanded the captive maiden Briseis from his rival, the warrior Achilles. The bitter quarrel that resulted between Achilles and Agamemnon became a major theme of the Greek epic the *Iliad.*

After Troy fell, Agamemnon returned to Mycenae with the Trojan princess Cassandra as his captive. Clytemnestra, aided by her lover, Aegisthus, killed Agamemnon and Cassandra out of revenge for what she thought was the death of Iphigenia. Orestes killed his mother and Aegisthus to avenge the murder of Agamemnon. F. Carter Philips

Agassi, *AG uh see,* **Andre** (1970-), became one of the dominant American tennis players of the late 1900's and early 2000's. He is known for his powerful forehand and two-handed backhand strokes as well as his ability to return an opponent's serve. Agassi is one of the most colorful players in men's tennis and one of the most popular. He has made many commercial endorsements that have spread his fame beyond the sports world.

Agassi became the fifth man to win all four grand slam tournaments during his career. He won the Wimbledon tournament in England in 1992, the U.S. Open in

1994 and 1999, the Australian Open in 1995, 2000, and 2001, and the French Open in 1999. Agassi also won the gold medal as men's singles champion at the 1996 Summer Olympic Games. In 2001, he married German tennis star Steffi Graf. Andre Kirk Agassi was born on April 29, 1970, in Las Vegas, Nevada. Dave Nightingale

Agassiz, *AG uh see,* **Louis** (1807-1873), was a Swiss-born naturalist who studied many kinds of animals in Europe and America. He became noted for his work on both modern and fossil forms of fishes. He established a zoological laboratory on an island in Buzzards Bay off the coast of Massachusetts to study animals in their natural surroundings. Agassiz believed that animal species do not change, and he criticized Charles Darwin's theories on evolution. As a geologist, Agassiz showed that glaciers once covered large areas of the earth.

Jean Louis Rodolphe Agassiz was born on May 26, 1807, in Motier-en-Vuly, Switzerland. He studied at the universities of Zurich, Heidelberg, and Munich. Agassiz came to the United States in 1846. In 1848, he became a professor of zoology and geology at Harvard University (see Geology [Experimental geology]). He died on Dec. 14, 1873. Carolyn Merchant

Agate, *AG iht,* is a banded form of *chalcedony,* a fine-grained, porous type of quartz. It occurs primarily as layers in the cavities of sedimentary rocks (see **Sedimentary rock**). Most types of agates are dully colored. Their bands vary from white through gray to black. In some cases, the bands may be pale red, yellow, or blue. The colors result from the presence of such impurities as iron oxide and manganese oxide. Agates differ in the pattern of their bands. *Onyx* is a type of agate distinguished by parallel bands that lie in a plane. The bands of *eye agate* form circles that spread out from the center. *Moss agate* has delicate moss-like patterns.

Lizzadro Museum of Lapidary Art (WORLD BOOK photo)

Moss agate

Agate is used chiefly in making ornaments, such as pins and brooches. Most agate that is used for ornaments must be colored artificially. Agate's hardness and ability to resist acids also make it valuable in the manufacture of mortars and pestles. Mortars and pestles are tools used to crush and mix chemicals. Most agate comes from quarries in Brazil and Uruguay. Idar-Oberstein, which is in southwestern Germany, has been the main center for cutting and polishing agate for several hundred years.

Robert W. Charles

Agate Fossil Beds National Monument is in northwestern Nebraska (see **Nebraska** [physical map]). It has the fossil bones of extinct animals that lived about 20 million years ago. The fossils include those of two-horned rhinoceroses and of animals that had horselike heads, rhinoceroslike forelegs, bearlike hindlegs, and clawed feet. The monument was authorized in 1965. For its area, see **National Park System** (table: National monuments). Critically reviewed by the National Park Service

Age of Reason was a period in history when philosophers emphasized the use of reason as the best method of learning truth. The period of the Age of Reason began in the 1600's and lasted until the late 1700's. The Age of Reason is also called the *Enlightenment* or the *Age of Rationalism.* Its leaders included several French philosophers—the Marquis de Condorcet, René Descartes, Denis Diderot, Jean-Jacques Rousseau, and Voltaire—and the English philosopher John Locke.

The leaders of the Age of Reason relied heavily on the scientific method, with its emphasis on experimentation and careful observation. The period produced many important advances in such fields as anatomy, astronomy, chemistry, mathematics, and physics. Philosophers of the Age of Reason organized knowledge in encyclopedias and founded scientific institutes. The philosophers believed that the scientific method could be applied in the study of human nature. They explored issues in education, law, philosophy, and politics and attacked tyranny, social injustice, superstition, and ignorance. Many of their ideas were taken up as the ideals of the American and French revolutions during the late 1700's.

The worship of reason. The philosophers of the Age of Reason believed human beings have a unique advantage over all other creatures because they can reason. The philosophers credited reason for all achievements in science and philosophy. They contrasted reason with ignorance, superstition, and uncritical acceptance of authority—all of which they felt had dominated the Middle Ages. They blamed people in authority, particularly Roman Catholic leaders, for keeping others in ignorance to maintain their own personal power.

The philosophers of the Age of Reason were greatly influenced by discoveries in the physical sciences, such as the law of falling bodies discovered by Galileo in Italy and the laws of gravitation and motion formulated by Sir Isaac Newton in England. The philosophers saw that great discoveries like these were made through mathematics. They believed that mathematics yielded absolutely certain conclusions because the process started with simple *axioms* (self-evident truths) and moved from one self-evident step to another. Using this method, scholars discovered laws of nature that otherwise would have remained unknown. As a result, the philosophers of the Age of Reason believed that mathematics was the model which all other sciences should follow.

Reason was thought to be the power that enables people to "see" mathematical truths just as clearly as they can see a hand before their eyes by visual perception. However, visual perception yields only *particular,* or *contingent,* truths. For example, it is not necessary that every hand have five fingers because one or more fingers could be lost in an accident. Only reason yields *necessary,* or *universal,* truths. An example of such a truth is that 5 plus 5 will always equal 10.

The philosophers of the Age of Reason believed that each person has a *rational will,* which makes it possible to make and carry out plans. Animals, they declared, are slaves of their emotions. When an animal is afraid of something, it tries to escape. When an animal is angry, it fights. However, people can figure out the best course of action when they are afraid, angry, or in trouble. In addition, people can make themselves do the right

thing, instead of doing only what may seem easier or more appealing.

The philosophers realized that people do not always plan ahead but often act on impulse, which they attributed to inadequate education. All people, the philosophers believed, are born with the capacity to reason. Descartes wrote that "the power of forming a good judgment and of distinguishing the true from the false, which is properly speaking what is called good sense or reason, is by nature equal in all men." Descartes therefore thought that to become rational, a person need only acquire an education that teaches a good method of reasoning.

Locke wrote that reason is "the candle of the Lord set up by Himself in men's minds" and "must be our last judge and guide in everything." Locke believed reason teaches that people must unite and form a state to protect their "lives and liberty and property." He noted that although people must give up some rights when they form a state, they gain more in protection than they lose.

Locke believed that anyone can reason, providing the capacity is allowed to develop. He therefore emphasized the importance of education and insisted on the right of free speech and on toleration for conflicting ideas.

The orderliness of nature. Philosophers of the Age of Reason believed that nature is vast and complex but well ordered. The English poet Alexander Pope described nature as "a mighty maze, but not without plan." The philosophers of the period felt that everything in the universe behaves according to a few simple laws, which can be explained mathematically. Their favorite example of such a law was Newton's law of gravity.

Human nature, the philosophers believed, is as well ordered as the physical universe. In *The Spirit of the Laws* (1748), the French philosopher Montesquieu wrote: "The material world has its laws, the intelligences superior to man have their laws, the beasts their laws, and man his laws." Montesquieu thought that a science of human nature was possible, and he became one of the first philosophers to try to formulate the basic uniformities of all human behavior.

Montesquieu believed that climate has an important influence on temperament and thus on conduct. According to Montesquieu, different kinds of government are appropriate for peoples who are living in different parts of the world. The best government for each nation could be planned, he felt, by considering the country's climate. Montesquieu thought, for example, that free governments are possible in northern latitudes. "People are more vigorous in cold climates," he wrote, and they have a "greater share of frankness and sincerity." But, Montesquieu said, the only workable form of government in a hot climate is *despotism* (rule by a dictator). Although his conclusions were discarded as mere speculation, they are typical of the Enlightenment's faith in reason.

Literature in the Age of Reason questioned accepted thinking. Writers portrayed human life as changeable and human understanding as partial. Much of the literature was written with self-consciousness and irony. It called attention to conventions and provoked skeptical awareness. The period reached its peak with works such as Pierre de Laclos' *Dangerous Liaisons* (1782) and the Marquis de Sade's *Philosophy in the Bedroom* (1795). In these novels, rational thought goes as far as possible toward separating the thinking individual from conventional influences and limitations.

Deism. The philosophers of the Age of Reason were convinced that the universe can be understood by the human mind. This is not an accident, the philosophers emphasized, because God could have created a universe too complex to be grasped by human beings. Instead, God created a universe ideally adjusted to the reasoning powers of people.

Most of the philosophers believed that after God had created the universe, He left it strictly alone. This theory, called *deism,* rules out the possibility of miracles or other special acts by God. According to deism, God regulated nature so that it proceeds mechanically. Future events are therefore fully predictable on the basis of earlier events. The philosophers liked to think of the universe as a clock that keeps perfect time because it was designed by a superior clockmaker. See **Deism**.

Influence of the Age of Reason. The thinkers of the Age of Reason formulated ideals of human dignity and worth. In France, unjust social and political conditions were criticized by a group of philosophers known as the *philosophes*. This group, which included Diderot, Rousseau, and Voltaire, greatly influenced leaders of the French Revolution. The philosophes and, more importantly, Locke also influenced the leaders of the Revolutionary War in America.

Philosophers of the Age of Reason sometimes disagreed on minor matters, but they all accepted the idea of the English philosopher Francis Bacon that "knowledge is power." Because they aimed, in Bacon's phrase, at "the improvement of man's estate," they concentrated their efforts on the advancement of knowledge. Their action explains why so many scientific institutes, including the famous Royal Society in England, were founded during the Age of Reason.

The urge to advance knowledge also explains why great effort was made to organize and circulate the results of the scientific research of the time. Many scholars gathered, organized, and published this knowledge. In fact, the Age of Reason could be called the "age of the encyclopedia." The most famous reference work was the French *Encyclopédie,* edited by Diderot and Jean d'Alembert, and completed between 1751 and 1772.

To the philosophers of the Age of Reason, progress in human affairs seemed assured. It was only a question of time, they believed, until people learned to let reason—not ignorance, emotion, or superstition—guide them. When people did so, they would be happy. Condorcet expressed this optimism in his *Sketch for a Historical Picture of the Progress of the Human Mind* (1793-1794).

Criticism of the Age of Reason. Today, many beliefs of the Age of Reason seem rather naïve. Most philosophers now believe that truths discovered by reason are universal only because they are *tautologies*. A tautology is a statement that merely repeats an idea in different words, without giving any new information. We can say, for example, that "all cats are felines." The statement is universally true, but only because "cat" means "feline."

If the rational truths of the Age of Reason are tautologies, they do not tell us anything about nature. They tell us only how words are used. Most philosophers of the

1900's believe that factual statements about the world are never certain. Such statements are only probable at best, and they may even be false.

The philosophers of the Age of Reason felt it was self-evidently true that governments should preserve their citizens' property. But in the 1800's, the German philosopher Karl Marx argued that this view merely reflected the prejudices of the middle class. These people own the property, said Marx, and thus want to preserve it.

The argument that universal truths are only tautologies was stated early in the Age of Reason by the English philosopher Thomas Hobbes. He wrote that reasoning is "nothing but reckoning, that is, adding and subtracting of the consequences of general names." But few people paid any attention to Hobbes's views, except to condemn them.

The Age of Reason's optimistic belief in a rational human will has also been challenged. In the early 1900's, for example, the Austrian physician Sigmund Freud stated that what we like to consider as "sound reasons" for our actions are only excuses. We act the way we do, Freud said, because of unconscious drives arising from a part of our subconscious mind called the *id*. We then attribute socially acceptable motives to ourselves to please another part of our subconscious, the *superego*.

The Age of Reason, however, ended long before Marx and Freud attacked its basic beliefs. Toward the end of the 1700's, a great change in people's outlook occurred. They came to value feeling rather than reason and to prefer passion, individuality, and spontaneity to discipline, order, and control. This change marked the beginning of the Romantic movement and the end of the Age of Reason. James Creech

Agee, *AY jee,* **James** (1909-1955), was an American writer. His Tennessee childhood provided the setting for his novel *The Morning Watch* (1951). *A Death in the Family* is a poetic novel based on his earliest years in Knoxville, his hometown. The work was published in 1957, after he died. It won the 1958 Pulitzer Prize for fiction. Tad Mosel adapted the novel into a play, *All the Way Home* (1960), which won the 1961 Pulitzer Prize for drama.

Agee collaborated with photographer Walker Evans on a study of white tenant farmers during the Great Depression. Evans's pictures and Agee's text were published as *Let Us Now Praise Famous Men* (1941). During the 1940's, Agee reviewed movies for *Time* and *The Nation* magazines. Beginning in 1948, he wrote several screenplays, including scripts for *The African Queen* (1951) and *The Night of the Hunter* (1955). His film reviews and essays were published in *Agee on Film* (1958). A second *Agee on Film* volume, published in 1960, has five of his screenplays. Collections of Agee's writings include *Collected Poems* (1968), *Collected Short Prose* (1968), and *Selected Journalism* (1985). Victor A. Kramer

Agency for International Development is an independent agency of the United States government that administers most of the nation's economic, technical, and humanitarian foreign aid programs. These programs are designed to improve the quality of life in developing countries in Africa, Asia, Latin America, and central and eastern Europe. The agency, which is commonly referred to as USAID or simply AID, helps these nations use their resources to become self-supporting.

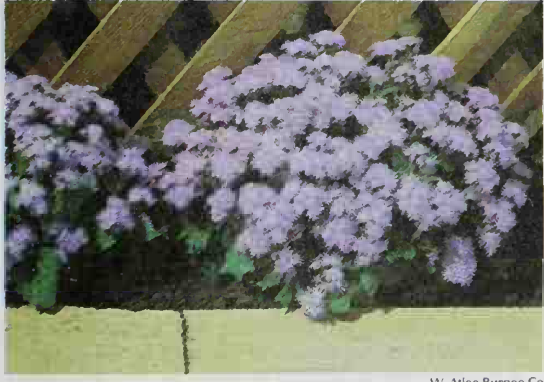
USAID works to improve education, farm and industrial production, health care, nutrition, and population planning. It gives loans and grants to build hospitals, housing, and schools, and to set up small businesses. It also funds communications systems, small factories, power plants, and rural roads. USAID also provides famine and disaster relief, including food, medical aid, and temporary housing, to any needy nation.

Congress created the agency in 1961. From 1979 to 1999, it was part of the International Development Cooperation Agency.

Critically reviewed by the Agency for International Development

Agent is a person who represents someone else in legal, business, or other matters. The person who employs the agent is called the *principal*. The agent's authority may be *express* or *implied*. Express authority involves doing exactly what the principal says to do. Implied authority involves doing anything that is a normal part of the agent's duties on behalf of the principal. For example, the president of a corporation is an agent of the corporation. He or she has implied authority to perform the customary acts of a president, even without express authority.

If the principal allows an agent to appear as if he or she has more authority than the agent really has, the principal is bound by what the agent does. If the agent acts without authority, the principal is under no obligation unless the principal takes advantage of the act or approves it in some other way. If the principal does not approve the act, the agent may be liable for damages to the person the agent misled. Edward J. Kionka



Agent Orange is the military code name for a weedkiller used by the United States during the Vietnam War (1957-1975). In the 1960's and early 1970's, the United States armed forces sprayed Agent Orange over jungles and farms in South Vietnam and Laos. Agent Orange was used to *defoliate* (cause the leaves to fall off) trees and shrubs and to kill crop plants. The spraying revealed enemy hiding places and destroyed food crops.

Agent Orange consisted of two weedkillers—2,4-D and 2,4,5-T. Some veterans blamed Agent Orange for health problems. In 1990, the Centers for Disease Control (now Disease Control and Prevention), a U.S. government agency, said it found no evidence that Agent Orange increased the risk of cancer among Vietnam veterans. That same year, a congressional committee declared the study flawed. In 1991, Congress passed a bill providing disability benefits for Vietnam veterans suffer-

ing from certain illnesses said to have been caused by exposure to Agent Orange. See Dioxin.

In 1993, the Institute of Medicine, an adviser to the U.S. government, released a study that linked exposure to Agent Orange to three kinds of cancer and two skin diseases. The study based its conclusions on civilians' exposure in their jobs or in job-related accidents. It recommended more studies before the effects of Agent Orange on veterans could be determined. Gary F. Bennett

Ageratum, *AJ uh RAY tuhm* or *uh JEHR uh tuhm,* is a popular, low-growing, annual plant of flower gardens. It is native to tropical regions of Central and South America. Its pale blue, white, or pink flowers bloom all summer. Each flower head has many tiny, tube-shaped flowers, crowded closely together. Ageratum plants may be grown from seeds started indoors in early spring, or planted later outdoors. W. Dennis Clark

W. Atlee Burpee Co.

The ageratum is a popular garden plant that blooms all summer. Each flower head has many tiny, tube-shaped flowers.

Scientific classification. Ageratum plants are in the composite family, Compositae. A common ageratum is *Ageratum houstonianum.*

Aggression is a term psychologists use to refer to behavior intended to hurt others. Aggression may take a direct form, such as verbal abuse or a physical attack against people or their possessions. Indirect methods of aggression include spreading rumors and stealing.

People become aggressive for various reasons. Experiencing pain or danger can lead to aggression. In other cases, people behave aggressively to gain status, money, pleasure, or control over others.

Different approaches to understanding aggression emphasize different *determining factors* (causes). *Biological factors,* such as genes and hormones, and *personality characteristics,* such as dominance or hostility, can lead to aggressive behavior. So can a person's *developmental history*—that is, how the person was raised. *Social factors,* including the presence of an audience and the sex, race, or other characteristics of the target, can also influence aggression.

Most theories of aggression recognize the relationship between emotions and aggression. People who experience frustration, anger, or fear may act aggressively. Some theories focus on *social learning,* the process by which individuals learn the behavior society expects of them. According to these theories, people may learn to be aggressive by witnessing aggressive behavior, such as family arguments and violent television programs. They may also learn aggression through *direct rewards* (getting what they want after acting aggressively). Social learning theories also emphasize the importance of *gender roles,* society's expectations about appropriate behavior for males and females. Deborah South Richardson

Agincourt, *AJ ihn kawrt,* **Battle of,** took place between English and French armies near the village of Agincourt, in northern France, in 1415. The English had only about 6,000 troops. But its archers, firmly disciplined and backed by cavalry, routed a French army that probably consisted of about 20,000 to 30,000 troops. The battle marked the third great English victory in the Hundred Years' War. The English went on to conquer Normandy and to sign the favorable Treaty of Troyes in 1420. The English playwright William Shakespeare wrote about the battle in his history play *Henry V.*

C. T. Allmand

Aging is the process of growing old. As adults age, they become increasingly vulnerable to injury, illness, and death. Aging is a characteristic of almost all living things. The rate at which it occurs, however, varies within and across species. The biological changes associated with aging begin at the moment of *conception* (fertilization). In most human beings, the changes do not become visible until individuals reach 30 to 40 years of age. Age-related changes include graying or loss of hair, weakened muscles, wrinkled skin, and diminished sense of hearing and vision.

Why people age. Early scientists and philosophers viewed aging as a natural process that removed the elderly to make room for the young. This idea suggests that the natural lifespan of an organism is fixed and determined by genetic instructions that are present at birth. However, many scientists now believe that aging is the result of various natural biological processes rather than a predetermined genetic program. Most scientists think that aging and death occur at different rates and times among individuals because of a combination of genetic variation, differences in the way in which people live their lives, and the random nature of the biological processes that contribute to aging.

For most organisms, the timing of death is linked to the time in the life span when reproduction occurs. The timing of puberty and menopause is particularly important. After the reproductive period, the cells, tissues, and other components of the body have accumulated enough damage so that they can no longer function as well as before. This loss of function is expressed in the form of a wide range of diseases and disorders associated with aging.

How aging occurs. Scientists do not fully understand the precise biological changes in cells, tissues, and organs that contribute to aging. One important mechanism involved in aging is the damage that accumulates in cells from unstable molecules called *free radicals.* These molecules are produced from the natural biological processes as the body works to maintain a constant

© Chuck Savage, Corbis

Exercise can help elderly people maintain or improve physical fitness. Although the process of aging cannot be prevented, regular physical activity can produce benefits at any age.

temperature and level of functioning.

The human body has many biological defense mechanisms designed to prevent or minimize free radical damage and repair the damage that does occur. Over time, however, the damage caused by free radicals accumulates and contributes to the many processes associated with aging. Scientists are looking for ways in which they can reduce or postpone the damage caused by free radicals and possibly delay the aging process.

Overcoming aging. Some of the effects of aging can be masked through the use of cosmetics, creams, lotions, and plastic surgery. Many people claim that vitamins, antioxidants, hormones, and various other substances have antiaging properties. Scientific research on these claims has yet to be completed, and most scientists doubt that they will work. However, scientific experiments have shown that it is possible to make some animals live longer by reducing their intake of food. Researchers are trying to understand how and why this method, called *caloric restriction,* works. Most scientists, however, believe that it is impossible to stop or reverse the process of aging. S. Jay Olshansky

Agnew, Spiro Theodore (1918-1996), became the only vice president of the United States to resign his office while under criminal investigation. In 1968 and 1972, Agnew had won election as vice president under President Richard M. Nixon. Agnew resigned in 1973 after a federal grand jury began hearing charges that he had participated in graft as an officeholder in Maryland.

Office of the Vice President

Spiro T. Agnew

Agnew had been elected governor of Maryland in 1966. He was the first man of Greek descent to serve as governor of an American state, or as vice president. He became the second vice president to resign. In 1832, Vice President John C. Calhoun resigned after being chosen to fill a U.S. Senate seat from South Carolina.

Early life. Agnew was born on Nov. 9, 1918, in Towson, Maryland. His father, Theodore Spiro Agnew, had come to the United States in 1897. Theodore Agnew became a leader of the city's Greek community.

Agnew studied chemistry for three years at Johns Hopkins University, and then transferred to the law school of the University of Baltimore. He served in the Army in Europe during World War II (1939-1945).

Agnew switched from the Democratic to the Republican Party after the war. He married Elinor Isabel Judefind in 1942. They had three daughters and a son. Agnew received a law degree in 1947 and began practicing in Baltimore County.

Political career. Agnew entered politics in 1957, when he was appointed to the Baltimore County Board of Appeals. In 1962, he was elected county executive, the chief official of Baltimore County. In 1967, Agnew became the fifth Republican governor in Maryland history.

Agnew was little known outside Maryland in 1968 when the Republican National Convention, at Nixon's request, nominated him for vice president. In the election, Nixon and Agnew defeated the Democratic candidates, Hubert H. Humphrey and Edmund S. Muskie. Agnew soon became well known and highly controversial. He often accused some newspapers and TV networks of presenting news in a way that was prejudiced against the administration. He also criticized student radicals and other dissenters. In 1972, Nixon and Agnew won a landslide victory over their Democratic opponents, George S. McGovern and Sargent Shriver.

In 1973, federal officials began to investigate charges that Agnew had accepted bribes from contractors in return for helping them get state government work in Maryland. The investigation covered the period Agnew had served as Baltimore County executive, Maryland

governor, and United States vice president.

Agnew repeatedly denied any wrongdoing. But on October 10, he resigned as vice president under an agreement with the Department of Justice. Agnew pleaded *nolo contendere* (no contest) to a single charge—that he had cheated the government of $13,551 on his federal income tax payment for 1967. The judge declared that the plea was "the full equivalent of a plea of guilty." Agnew was fined $10,000 and sentenced to three years of unsupervised probation.

House Minority Leader Gerald R. Ford succeeded Agnew as vice president. Ford was sworn into the office on Dec. 6, 1973.

In 1974, the Maryland Court of Appeals disbarred Agnew because of his *nolo contendere* plea. The court's action prohibited Agnew from practicing law in the state. In 1981, another Maryland court ordered Agnew to pay the state the amount of the bribes it declared he had accepted, plus interest. In 1983, Agnew paid Maryland $268,482. The former vice president died on Sept. 17, 1996. Earl Mazo

Agnon, *AHG nahn,* **Shmuel Yosef** (1888-1970), was an Israeli author. He shared the 1966 Nobel Prize in literature with German-born author Nelly Sachs.

Agnon wrote novels and short stories about Jewish life in Europe and Israel. His fiction has profound mystical and psychological overtones, combining social satire with religious themes. Agnon, who wrote in Hebrew, used language and storytelling techniques drawn from Jewish religious texts and folk literature.

Shmuel Yosef Czaczkes was born on July 17, 1888, in eastern Galicia, now part of Ukraine. He first went to Palestine in 1907 and later changed his name to Agnon, which he took from the title of his first published story, "Agunot" ("Deserted Wives," 1909). Agnon's major novels include *The Bridal Canopy* (1931), *A Simple Story* (1935), *A Guest for the Night* (1937), and *Yesteryear* (1945). Some of the author's short stories were collected in *Twenty-One Stories* (1970). Agnon died on Feb. 17, 1970.

Stanley L. Nash

Agnosticism, *ag NAHS tuh sihz uhm,* is the belief that ultimate questions, especially those about the existence of God, cannot be answered. The term comes from the Greek word *agnostos,* which means *not knowing.* It was first used by the British naturalist Thomas Henry Huxley in 1869. Agnosticism reflects the point of view that reason and scientific evidence should be the sole guides to finding truth. During the mid-1900's, the German-American theologian Paul Tillich argued that a period of agnosticism—in the form of doubt—is a necessary stage before one can accept a meaningful faith. See **Atheism; Ingersoll, Robert Green.** Mark Juergensmeyer

Agouti, *uh GOO tee,* is a rodent that lives in dense forests from southern Mexico to northern Argentina, and in the West Indies. Agoutis measure almost 2 feet (60 centimeters) long. They have small rounded ears, long legs, and either a short tail or no tail at all. Most agoutis have brown, blackish-brown, or orange fur. The hair on the back is grayish. Agoutis run with a jumping motion, like deer.

Agoutis eat fruit, leaves, and roots. Most females bear their young in litters of two. The young have full coats of fur at birth, and their eyes are open. They can move about and take care of themselves soon after birth. However, they remain with their parents for as long as 20 weeks. Coatis, mountain lions, and jaguars prey on agoutis. In the tropics, people hunt agoutis for their meat. Agoutis make affectionate pets. Charles A. Long

© Giuseppe Mazza

The agouti is a rodent that lives in forests of Central and South America and the West Indies. It eats fruit, leaves, and roots.

Scientific classification. Agoutis belong to the paca and agouti family, Dasyproctidae. They belong to the genus *Dasyprocta.*

Agra, *AH gruh* (pop. 1,259,979), is one of the largest cities in Uttar Pradesh, a state in northern India (see **India** [political map]). It is also one of the oldest cities on the Indian Peninsula. Agra is famous as the site of the Taj Mahal. In the 1600's, Emperor Shah Jahan ordered this magnificent marble tomb built as a memorial to his wife, Mumtaz-i-Mahal. Agra lies on the Yamuna River. The city centers around Agra Fort, which was built by the Mughal emperor Akbar about 1566. The northern part of the city has business and market districts. Modern factories lie north of the city along the river. Agra is an important trading center for cotton, grain, sugar, and tobacco. The city is well known for the gold lace and delicate inlaid mosaics that its people make chiefly by hand.

Agribusiness, *AG ruh BIHZ nihs,* is the group of industries involved in producing, transporting, processing, distributing, and selling farm products. It also includes those businesses that supply farmers with such goods and services as machinery, seeds, fertilizers, agricultural chemicals, credit, and management information.

Agribusiness is one of the most rapidly growing industries in the United States. Although farmers make up only about 3 percent of the U.S. labor force, nearly 1 American worker out of every 4 is employed in some branch of agribusiness.

Improved technology and specialization have contributed to the growth of agribusiness. In the past, farm families produced nearly everything they needed on the farm itself. But farmers today buy many of the products they use from others. For example, as farmers began to use pesticides and herbicides, a need for more workers in the chemical industry was created. Warren F. Lee

Agricola, *uh GRIHK uh luh,* **Gnaeus Julius,** *NEE uhs* (A.D. 37?-93), was an able Roman general. He was given command in Britain by the emperor Domitian about A.D. 77 and ordered to complete the conquest of England. Seven years later, Agricola had conquered all of England and a part of Scotland. He also sent ships around the island of Great Britain to draw maps. Agricola then prepared to invade Ireland. But Domitian was displeased by the high cost of Agricola's operations. Agricola was relieved of his command and recalled to Rome. Agricola was born in what is now Frejus, France. He owes much of his fame to the writings of his son-in-law, the historian Tacitus. Arther Ferrill

Agricultural Adjustment Administration (AAA). See New Deal; Parity.

Agricultural education is instruction about crop production, livestock management, soil and water conservation, and various other aspects of agriculture. Agricultural education includes instruction in food education, such as nutrition. Agricultural and food education improves the quality of life for all people by helping farmers increase production, conserve resources, and provide nutritious foods.

There are four major fields of agricultural education: (1) elementary agriculture, (2) vocational agriculture, (3) college agriculture, and (4) general education agriculture. Elementary agriculture is taught in public schools and deals with such subjects as how plants and animals grow and how soil is farmed and conserved. Vocational agriculture trains people for jobs in such areas as production, marketing, and conservation. College agriculture involves training of people to teach, conduct research, or provide information to advance the field of agriculture and food science in other ways. General education agriculture informs the public about food and agriculture.

In the United States

There are three chief sources of agricultural education in the United States. They are (1) high schools, (2) colleges and universities, and (3) youth organizations.

High schools in every state, the District of Columbia, Puerto Rico, and the Virgin Islands provide vocational agriculture training. Most high school agriculture courses offer both classroom instruction and practical experience. For example, a student might raise a crop or an animal, work on a farm, or work for an agriculture business, such as a machinery dealer. Many schools offer adult education courses to help people improve their production, management, and computer skills.

Colleges and universities award bachelor's, master's, and doctor's degrees in agriculture.

Land-grant universities award more than three-fourths of all agricultural degrees. These state schools receive federal aid under legislation that followed the Morrill Act of 1862, which granted public lands to support agricultural or mechanical education. Land-grant universities have three chief functions: (1) teaching, (2) research, and (3) extension service.

Teaching. Colleges of agriculture prepare students for careers in all aspects of the food and agriculture system. Some career choices include food science and veterinary science, farming, ranching, teaching, marketing, management, and social services.

Research. Each land-grant university has an agricultural experiment station equipped with laboratories and experimental farms. There, agricultural scientists work to develop better farming methods, solve the special problems of local farmers, and provide new technology.

Extension service. The Cooperative Extension System is a partnership of the federal, state, and county governments. This service distributes information gathered by the land-grant universities and the U.S. Department of Agriculture to farmers, families, and young people. County extension agents, who work in most counties, train and support volunteer leaders. Agents and volunteers carry out extension programs through meetings, newsletters, radio, television, and visits.

David Frazier

Agricultural education prepares students for careers in livestock management, crop production, and other areas of agriculture. In this photograph, a teacher shows students how to evaluate the quality of hay used for livestock feed.

Youth programs and organizations involved in agricultural education include 4-H and FFA (Future Farmers of America). Members of 4-H participate in projects dealing with conservation, food and agriculture, health and safety, and other subjects. The 4-H program in the United States is part of the Cooperative State Research, Education, and Extension Service.

FFA is an integral part of the program of vocational agriculture in many high schools. Local chapters take field trips and conduct projects to develop leadership, citizenship, patriotism, and excellence in agriculture.

History. The rapid growth of agricultural education began during the late 1800's. In 1862, Congress created the Department of Agriculture to gather and distribute agricultural information. The Morrill Act, which provided for the land-grant schools, became law that same year. The Hatch Act of 1887 gave federal funds to establish agricultural experiment stations.

Government support for agricultural education increased during the 1900's. For example, the Smith-Lever Act of 1914 created what is now the Cooperative Extension System. The Smith-Hughes Act of 1917 and the George-Barden Act of 1946 financed high school instruction in farming. The Vocational Education Act of 1963 funded training in other fields of agriculture.

Agricultural science and education expanded after 1900 in response to a need for more technical knowledge and skill. This development led to the use of modern farming methods that required fewer farmworkers. Another major result of this change was the creation of larger farms and ranches. This development increased the need for more agriculture science and education.

In other countries

Agricultural education in other countries resembles that in the United States. Canada has its own 4-H program. Agriculture Canada distributes information on new farming methods and maintains experimental farms and research institutions throughout the country. In Australia, each state has several agricultural research stations and an extension service. The United Kingdom has a program of youth clubs called Young Farmers' Clubs. The Food and Agriculture Organization of the United Nations works to train people throughout the world in modern farming. The United States aids farmers in developing nations through its Agency for International Development (AID). Raymond J. Miller, Jr

Agricultural experiment station is a research center that conducts scientific investigations to solve problems and suggest improvements in the food and agriculture industry. Experiment station scientists work with farmers, ranchers, suppliers, processors, and others involved in food production and agriculture. Station scientists also work with natural resource and environmental organizations and with rural communities. Agricultural experiment stations have made outstanding contributions to the development of food and agriculture in the United States and Canada.

The United States has dozens of stations, including stations in the Virgin Islands and Puerto Rico. Each state has at least one main station at a state school called a *land-grant university.* Many states have branch stations to meet the needs of different climate and geographic zones in those states.

The United States stations are state institutions, but the federal and state governments cooperate in funding the research done at the stations. The states provide most of the government money. Additional income comes from grants, contracts, and the sale of products.

Station scientists study biological, economic, and social problems of food, agriculture, and related industries in each state. They investigate such subjects as crop variations, soil testing, livestock processing, and animal rations. They also work to develop and apply computers, biotechnology, and other advanced technology to food and agriculture. The scientists work with specialists called *extension agents,* who teach farmers about developments in agriculture. Most station scientists are faculty members of the land-grant universities.

The first state agricultural experiment station in the United States was organized in 1875 at Wesleyan University in Middletown, Connecticut. It was supported by private donations and state funds. Federal aid for experiment stations across the country began with the Hatch Act of 1887. The provisions of this act and later legislation providing increased funds were combined in the Hatch Act of 1955. The McIntire-Stennis Act of 1962 authorized forestry research at experiment stations. The federal government takes part in the experiment station program through the Cooperative State Research, Education, and Extension Service of the U.S. Department of Agriculture. The department coordinates research activities among the state experiment stations.

In Canada, about 50 percent of the experiment stations are controlled by the Canadian government. The Central Experimental Farm in Ottawa is the headquarters of the federal system. Private industries, universities, and agricultural colleges control the remainder of the stations. Each province has a number of provincial stations.

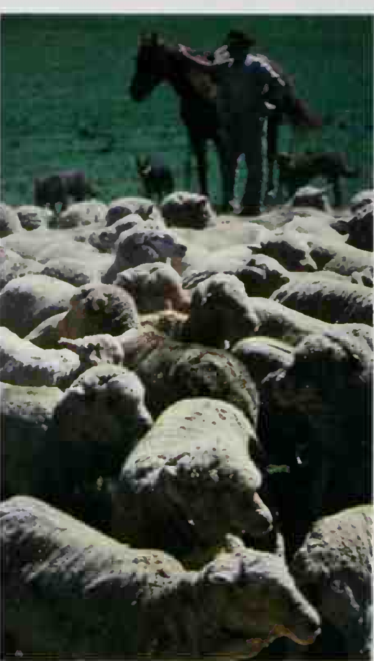
Agricultural Revolution. See Agriculture (The Agricultural Revolution).



Agricultural Stabilization and Conservation Service (ASCS) was an agency of the United States Department of Agriculture from 1961 to 1994. The service administered programs concerning farm products and agricultural conservation. It granted loans to farmers; purchased farm products from farmers and processors; administered acreage allotment and marketing quota programs; shared the cost of conservation and environmental protection measures with farmers and ranchers; and supervised civil defense activities relating to food. It also managed the inventories of the Commodity Credit Corporation (see Commodity Credit Corporation). The service was incorporated into the Department of Agriculture's Farm Service Agency in 1994.

M. Stone, DPI

Herding sheep in Australia

The vast and varied world of agriculture provides us with nearly all our food, with fibers for clothing, and with raw materials for industry. Half the world's workers are farmers, and about a third of the earth's land area is used for agriculture.

Agriculture

Agriculture is the world's most important industry. It provides us with almost all our food. It also supplies materials for two other basic human needs—clothing and shelter. In addition, agriculture provides materials used in making many industrial products, such as paints and medicines. About half the world's workers are employed in agriculture—far more than in any other industry.

Agriculture is one of the world's oldest industries. It began to develop about 10,000 years ago in the Middle East. At that time, certain Middle Eastern tribes discovered how to grow plants from seeds and how to raise animals in captivity Soon after the tribes mastered these skills, they began to depend chiefly on farming for food.

Before the development of agriculture, people got all their food by gathering wild plants, hunting, and fishing. They had to search for food continually, which left them little time for other activities. But as agriculture developed and farm output increased, fewer people were needed to produce food. The nonfarmers could then develop the arts, crafts, trades, and other activities of civilized life. Agriculture therefore greatly affected the food supply and made civilization possible.

Farmers provided more food than hunters and gatherers could supply. But for many centuries, improvements in agriculture came slowly. Farming depended heavily on human and animal labor, and farmers had few tools to make their land and labor more productive. Then in the late 1600's, inventors began to develop machines for planting, cultivating, and harvesting crops. Over the years, farm machinery has been steadily improved.

Since the early 1900's, scientists have developed better breeds of livestock, better varieties of plants, and highly effective fertilizers and pesticides. All these improvements have greatly reduced the need for farm labor and have enormously increased farm output.

However, nearly all the scientific improvements in agriculture have occurred in industrialized nations. In many nonindustrial countries, people farm much as their ancestors did many years ago. Countries that use old-fashioned farming methods have great difficulty increasing their production of food. But increased food production is necessary to keep up with today's rapid population growth. Helping the nonindustrial nations modernize their agriculture is one of the major challenges of the industrial nations.

This article discusses the world's chief agricultural products, the various kinds of agriculture that farmers practice, and the characteristics of agriculture around the world. The article also traces the history of agriculture. To learn about modern farms, see **Farm and farming**. For information on particular agricultural subjects, see the *Related articles* at the end of this article.

Larry D. Trede, the contributor of this article, is an Associate Professor in the Department of Agricultural Education and Studies at Iowa State University.

Chief agricultural products

Food is by far the most important farm product. But farms also provide many other products, from natural fibers to ornamental flowers and trees. Some crops are used only to feed livestock. These *forage* crops include alfalfa; clover; and many grasses, such as brome grass and timothy. Forage crops are important because they make commercial livestock production possible.

Food products. Farms provide almost all the world's food, including some fish and game. Most food products come from crops. The rest come from animals, especially cattle, hogs, poultry, sheep, and other livestock.

From crops. The world's farmers grow about 85 major food crops. They can be divided into eight groups. The main group is *cereal grains.* Grain is grown on half the world's cropland and supplies much of the nourishment in the human diet. The chief grains are barley, corn, millet, oats, rice, rye, sorghum, and wheat.

Various *root crops* make up the second most important group of food crops. Like cereal grains, root crops are grown throughout the world and are a basic food for many people. The leading root crops are potatoes, sweet potatoes, and a tropical plant called *cassava.*

The six remaining groups of major food crops are: (1) *pulses,* which consist mainly of dry beans and dry peas; (2) fruits and vegetables other than root crops and pulses; (3) oil-bearing crops, such as soybeans and coconuts; (4) sugar-bearing crops, especially sugar cane and sugar beets; (5) nuts; and (6) cocoa beans, coffee, and tea. Some oil crops, especially soybeans, are used to make flour and meal as well as oil.

From animals. Cattle, chickens, goats, hogs, sheep, turkeys, and other livestock are the main animals raised for food. Livestock are raised in every country and supply nearly all the world's meat, eggs, and milk. Farmers also raise other animals for food. For example, many farmers keep bees for honey. Farmers on *fish farms* raise freshwater food fish, such as catfish and trout, and saltwater shellfish, such as mussels and oysters.

Natural fibers come from a variety of plants and animals raised on farms. Mills and factories use the fibers to make fabrics, yarn, and other textile products.

Cotton, flax, hemp, jute, and sisal are the chief plant fibers. Wool, the principal animal fiber, comes mainly from sheep but also from such animals as goats and members of the camel family. Silk fibers are obtained from the cocoons of silkworms. Farms in Japan and China raise most of the world's silkworms. The development of nylon and other synthetic fibers since the early 1900's has reduced the demand for natural fibers in some countries.

Other agricultural products. Many farms provide other raw materials for industry besides fibers. These materials include natural rubber; animal hides, which are used to make leather; and such vegetable oils as castor oil and linseed oil. These oils are used in a variety of products, from paints to medicines. Some farmers grow trees for timber, though most timber comes from natural forests. Many farmers raise tobacco. Others grow ornamental flowers, trees, and shrubs. A few farmers raise such animals as foxes and mink for their fur.

Leading groups of agricultural products

Product groups	Production in tons*	Production in metric tons*	Leading countries
Cereal grains	2,253,295,000	2,044,155,000	
Corn	661,358,000	599,974,000	Brazil, China, United States

Kinds of agriculture

Farmers practice many kinds of agriculture. Each kind can be classed in a number of ways. Climate is a common basis for classification. For example, the kinds of farming practiced in the tropics can be classed as *tropical* agriculture. Similarly, many of the kinds of farming practiced in cooler regions can be classed as *middle-latitude* agriculture. Most kinds of agriculture can also be classed according to the amount or value of the goods produced per unit of land. Classified in this way, agriculture is *intensive* or *extensive.*

Intensive agriculture is practiced chiefly where farmland is scarce. It requires large amounts of fertilizer, labor, or other resources. Each unit of land is thus made as productive as possible. Small *truck farms* (vegetable farms) and orchards are examples of intensive agriculture. A truck farm may cover only 1 acre (0.4 hectare). But it may produce thousands of dollars' worth of vegetables yearly.

Farmers practice extensive agriculture where land is plentiful, rainfall is light, and the soil is not especially fertile. Extensive agriculture requires relatively little investment in equipment and supplies per unit of land, and each unit yields a relatively low return. The vast sheep ranches of Australia are an example of extensive agriculture. A ranch may cover 40,000 acres (16,000 hectares) or more and raise thousands of sheep. But each animal needs about 4 acres (1.6 hectares) of land for grazing. The return per unit of land is therefore only a few dollars' worth of wool or meat yearly.

The many kinds of agriculture can also be classified as either *commercial* or *subsistence.* Commercial farms produce crops and animals chiefly for sale. Subsistence farmers produce goods mainly for themselves. The following discussion deals with this classification.

Commercial agriculture

The great majority of farms in industrialized countries are commercial farms. They can be divided into two main groups: (1) specialized farms and (2) *diversified* (variety) *farms.*

Specialized farms earn all or most of their income from the sale of one kind of crop or livestock. Many of these farms use mass-production methods and require a large investment in equipment and supplies.

Specialized crop production. Crops produced for sale are called *cash crops.* Many commercial farms raise only one cash crop. These farms are known as *one-crop,* or *single-crop,* farms. Much of the world's wheat is grown on huge one-crop farms on the North American Great Plains and in Ukraine. Large single-crop farms in tropical and subtropical areas are often called *plantations.* Plantations raise such crops as bananas, coffee, rice, sugar cane, and tea. Other specialized farms raise two or more cash crops, though most of their income comes from one crop. Major crops raised on such farms include cotton, tobacco, oilseeds, and various grains.

Specialized livestock production. The main kinds of specialized livestock farms include cattle and sheep ranches, and dairy, poultry and egg, and hog farms.

Most cattle and sheep ranches consist mainly of graz-

ing land. In some major beef-producing countries, such as Argentina and Australia, cattle are kept on ranches until they are to be slaughtered. In the United States, Canada, and a few other countries, most ranchers ship their cattle to feed lots after the animals are 5 to 12 months old. Feed lots can feed cattle for market much faster than the animals can be fattened on the range. The typical feed lot practices highly intensive agriculture and can feed thousands of cattle on a very small area of land. The animals are kept in pens and given large amounts of grain and other high-energy feed.

Dairy farms specialize in raising milk cows. The typical dairy farm is much larger than a poultry farm but far smaller than a ranch. Most dairy farmers raise their own feed crops. But many others buy their feed.

Most poultry and egg farms are also highly intensive. Such a farm may cover only about 1 acre (0.4 hectare). Yet it may raise 20,000 or more laying hens or broiler chickens at a time. The birds are kept in temperature-controlled buildings and given high-energy feed.

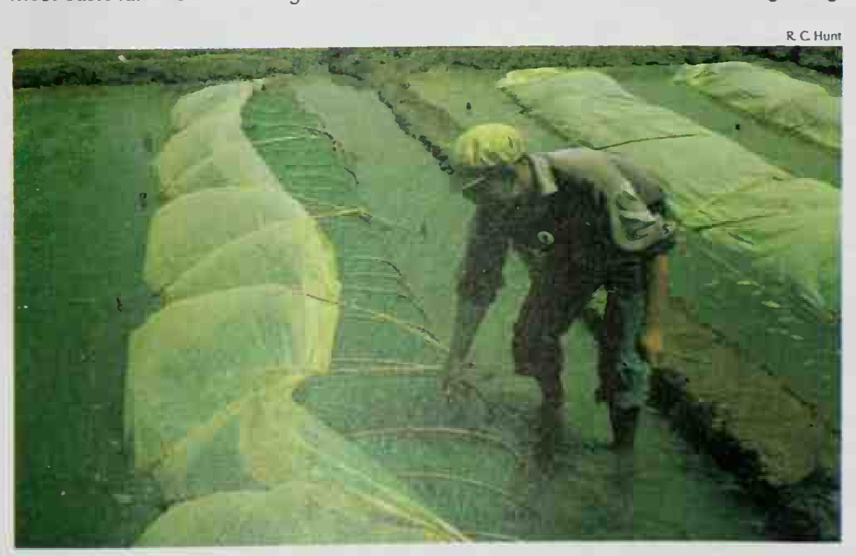
At a hog farm, the animals may be kept in buildings and concrete yards, or in dirt yards or pastures. A hog's diet consists primarily of corn and other grains.

Diversified farms raise a variety of crops and livestock. Such farms produce crops to sell and to feed their livestock. Most farms in Europe and many in the Midwestern United States are diversified farms.

Diversified farming is less risky than specialized farming. Bad weather, insects, or disease may ruin a year's output on a specialized farm. Or the market price for a particular product may decline sharply. But on a diversified farm, losses from one product may often be covered by profits from other products.

Subsistence agriculture

Millions of farm families in Africa, Asia, and Latin America produce barely enough food to *subsist* on—that is, to meet their own needs. Subsistence farming depends heavily on human labor and requires only the most basic farm tools. Although subsistence farmers produce goods chiefly for themselves, they may also raise small amounts for sale. This type of farming is often called *semisubsistence agriculture.*



Most subsistence farmers have one or more small plots of land, which they farm year after year. Such farms are common in the rice-growing regions of southern Asia and in parts of Africa and Latin America.

In some countries, many subsistence farmers do not have permanent farms. Instead, they live in groups that move from place to place within a large area fixed by custom. At each stop, the members of the community establish temporary farms. The number of such communities has declined since the mid-1900's. But large communities still exist in certain parts of the world. They practice two main kinds of farming: (1) shifting cultivation and (2) nomadic herding.

Shifting cultivation is an ancient farming method. It is widely used on the grasslands and in the forests of central Africa, northeastern South America, and parts of Southeast Asia. The soil in most of these regions is not particularly fertile. But to keep it as fertile as possible, a farm community grows crops on the same land for only a year or two. The community then cultivates an adjoining area or moves to a different part of its territory. At each new location, the grass and trees are cut down and burned. For this reason, shifting cultivation is also called *slash-and-burn* agriculture. Ashes from the burned grass and trees fertilize the soil. The abandoned land returns to grass or forest and can be farmed again.

Nomadic herding has long been practiced in desert regions of Africa and Asia. These regions are far too dry to grow crops. But they have enough wild grasses to support small herds of camels, sheep, goats, and other livestock. Tribes of desert nomads keep such herds to provide the necessities of life. The nomads depend on their animals for milk, cheese, and meat. And they live in tents and wear clothing made from the skins and hair of the animals. A tribe settles in an area until their livestock have stripped it of grass. The tribe and its herd then move on to a fresh grazing area.

R. C. Hunt

Intensive agriculture is practiced mainly where farmland is scarce, as in this rice-growing area outside Beijing. By using large amounts of such resources as labor and water, Chinese farmers make each unit of land as productive as possible.

Agriculture around the world

About 12 billion acres (4.8 billion hectares) of land—more than a third of the earth's total land area—are used for farming. Farmers grow crops on about a third of this land. Farmers use the rest of this land for raising livestock.

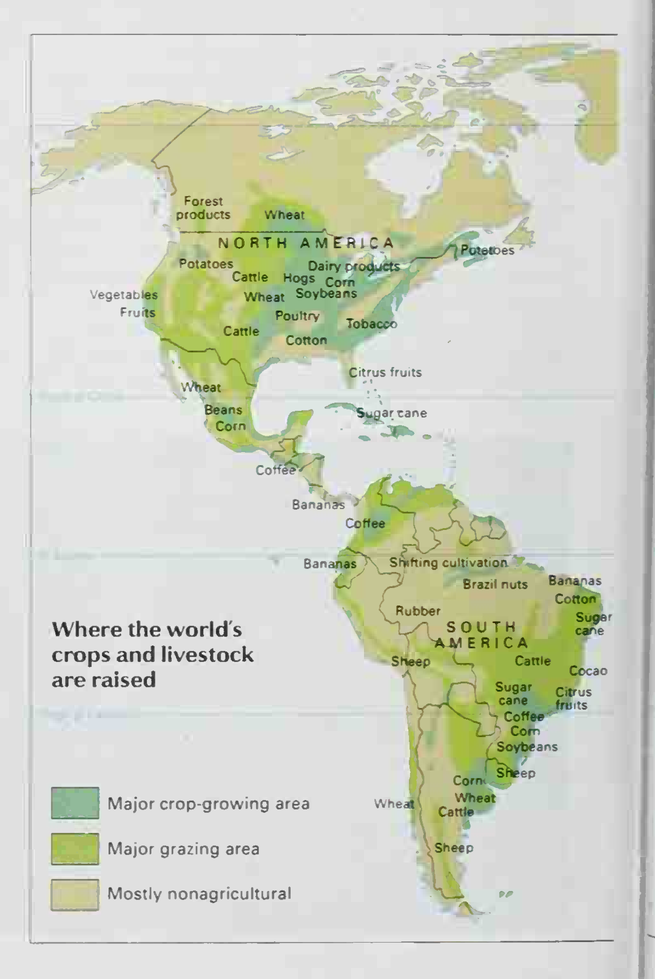
To grow crops, farmers need fairly level land and *tillable* (workable) soil. In addition, the climate must provide a certain amount of warmth and moisture. For example, most crops need a frost-free period, or *growing season,* of at least 90 days to develop from seeds into mature plants. Many crops require much longer. Except for the Far North and Antarctica, most regions of the world have a growing season long enough for at least some crops. However, many of these regions receive less than 10 inches (25 centimeters) of rain a year. Few crops can grow in such dry climates without irrigation.

Climate also largely determines the kinds of crops a farmer can grow. Such crops as bananas and cocoa beans grow well only in a tropical climate. Other crops, such as potatoes and apples, need a cooler climate. Many plants, including both bananas and potatoes, require much moisture. However, some plants, such as sorghum and wheat, grow best in a climate that is fairly dry.

Over the centuries, many methods have been developed to grow crops in unfavorable areas. By using irrigation, for example, farmers can raise crops even in some extremely dry places. Where the land is hilly, farmers build *terraces* by carving strips of level land out of the hillsides. Greenhouses enable farmers in areas with cold winters to grow certain fruits and vegetables the year around. Since the early 1900's, scientists have developed many plant varieties and livestock breeds to suit the soil or climate of particular areas.

This section discusses agriculture in North America and the other major regions of the world. For additional information, see the *Agriculture* section of individual continent and country articles.

The United States



Farmland covers about half the area of the United States—that is, nearly 1 billion acres (405 million hectares). The United States has about 465 million acres (188 million hectares) of cropland, more than any other country in the world. The remaining U.S. farmland is used for raising livestock.

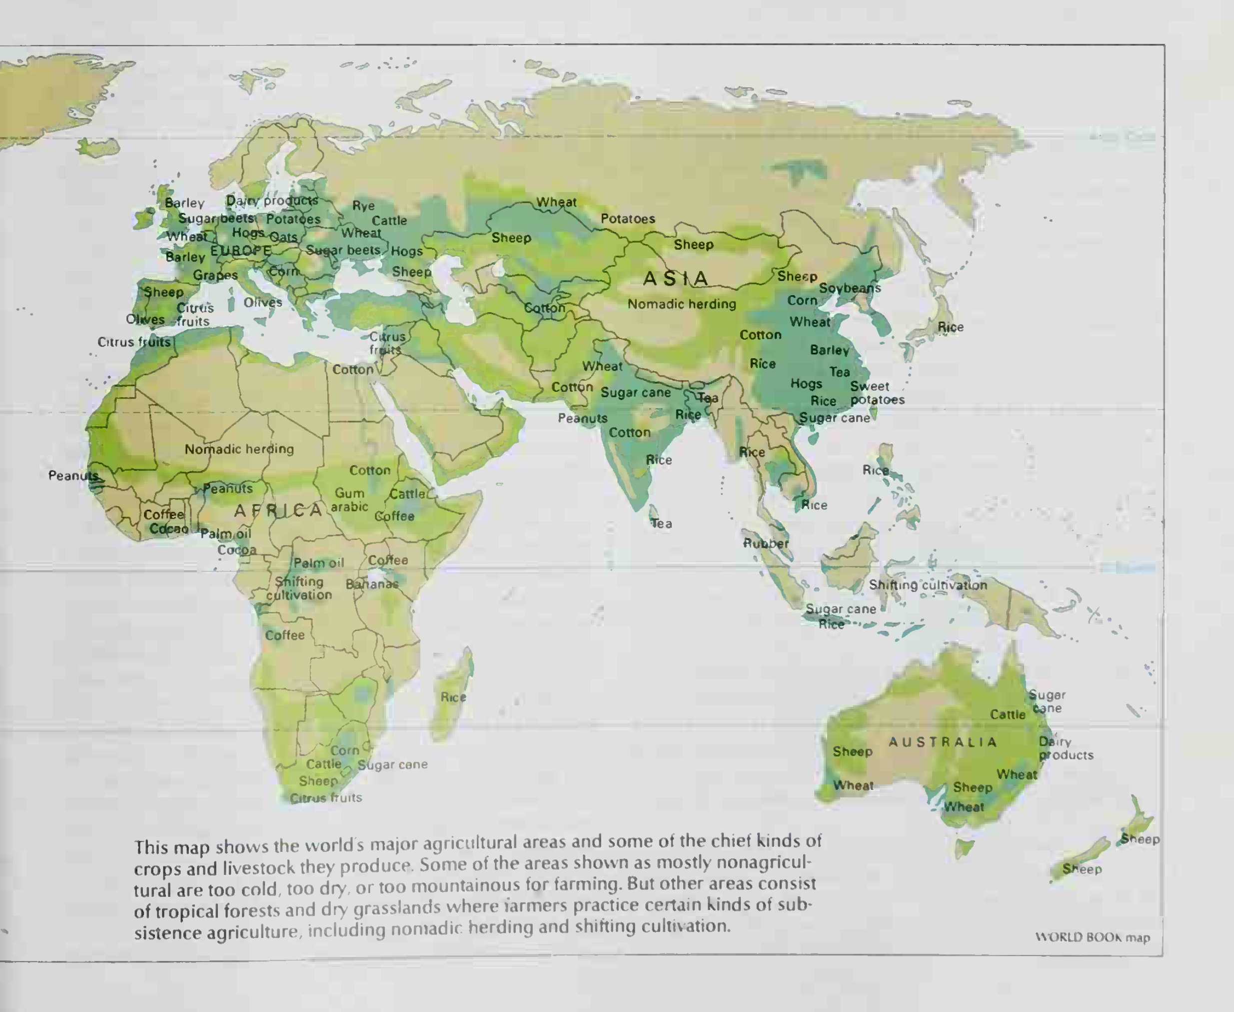
Only about 2 percent of all American workers are employed on farms. Yet the United States produces much of the world's farm output, including 25 percent of the beef and 15 percent of the grain, milk, and eggs. American farmers can produce such great quantities of food for two main reasons. These reasons are (1) the United States has vast areas of fertile soil, and the climate in many of these areas is ideal for agriculture, and (2) American farmers use scientific farming methods and much farm machinery.

Major agricultural regions. Certain regions of the United States are known for particular farm products. The Midwestern States, for example, are famous as the center of U.S. corn and hog production. More than two-thirds of the nation's wheat is grown in the Great Plains region and the Pacific Northwest. But because of the many scientific improvements in agriculture, many farm goods that were formerly associated with a particular region of the United States are now produced over a much wider area.

The center of cotton production, for example, has shifted from the Southern States to irrigated farmland in the Southwest. The broad grasslands of the West were once the nation's chief cattle-grazing areas. But the development of special breeds of cattle and new species of grass has helped create major grazing areas in the Southern States. Dairy farming was once concentrated in a region that extended from New York to Minnesota. But large, productive dairy farms are now found in every state of the nation.

The organization of U.S. agriculture. The United States has about 2,100,000 farms. They average about 473 acres (191 hectares) in size. Most farmland in the United States is privately owned. The federal government owns much grazing land in the Rocky Mountain and Great Plains regions. The government leases most of this land to ranchers.

Where the world's crops and livestock are raised



Since the 1920's, the number of farms in the United States has decreased steadily, while the average size has increased. The number of full-time farmers has also declined. Today, most operators of small farms also have nonfarm jobs. About two-thirds of all American farmers receive more than half of their total income from such sources.

About 500,000 U.S. farms—less than a fourth of the total number—account for over 80 percent of the cash receipts from the sale of farm products. Many farmers sell their products under an arrangement called *contract farming.* In contract farming, a farmer signs a contract with a food-processing or grain-marketing firm. Under most contracts, the farmer agrees to supply the contractor with a certain amount of the farm's output at a specified price. Most of the nation's broiler chickens and milk—as well as much of its beef, eggs, fruits, and vegetables—are produced under contract.

Organized support for U.S. agriculture is provided by farm organizations, government agencies, and extension services. A large number of farmers belong to *marketing cooperatives,* which work to find profitable markets for their members' products. Since the early 1960's, *commodity organizations* have also become important among farmers. Each organization represents the economic interests of farmers who specialize in a particular product, such as cattle, hogs, corn, soybeans, or wheat. Commodity organizations try to improve market conditions through product promotion, by funding research, and by promoting favorable legislation.

A number of general farm organizations also work to advance the interests of farmers. These groups include the American Farm Bureau Federation, the National Farmers Organization, the National Farmers Union, and the National Grange. Since the late 1960's, several labor unions have tried to organize U.S. farmworkers. But except in the Pacific Coast States, the drive has had only limited success.

Government plays an important role in United States agriculture. Federal and state laws deal with such matters as minimum farm prices preservation of the environment, quality standards for farm products, and the inspection of food. Government agencies enforce these laws and administer government farm programs. The

This map shows the world's major agricultural areas and some of the chief kinds of crops and livestock they produce. Some of the areas shown as mostly nonagricultural are too cold, too dry, or too mountainous for farming. But other areas consist of tropical forests and dry grasslands where farmers practice certain kinds of subsistence agriculture, including nomadic herding and shifting cultivation.

WORLD BOOK map

Leading agricultural states

Figures are for 1999 and include government payments.
Source: U.S. Department of Agriculture.

United States Department of Agriculture (USDA) is the chief federal agricultural agency (see **Agriculture, Department of**). Other federal agencies sponsor special agriculture programs. Almost every state also has its own department of agriculture.

Every state has an *extension service,* and nearly every county has *extension agents,* both of which are part of the Cooperative Extension System. These services and agents provide farm families with up-to-date information about farming techniques and methods of farm management. The Cooperative Extension System is a partnership of the federal, state, and county governments.

The state and county extension services are operated in connection with *land-grant universities.* Every state has at least one of these schools. Over the years, land-grant universities have become the nation's chief centers of agricultural education. Each land-grant university also operates an agricultural experiment station with the help of the federal government. The stations are the leading centers of agricultural research in the United States.

Careers in U.S. agriculture. Many agricultural careers are directly related to farming and ranching. But the number of U.S. farms and farmers has declined over the past few decades. Even so, many specialized areas in agriculture are growing very rapidly. These areas include biotechnology, communications, education, management, sales, and science.

Farmworkers include self-employed farmers and hired managers, supervisors, and laborers. Many people who plan to become farmers or farm managers attend an agricultural college. Some young people prepare for agricultural occupations by taking special courses in high school and participating in such extracurricular activities as 4-H and FFA (Future Farmers of America) groups (see **Agricultural education; FFA; 4-H**). A majority of supervisors receive their training on the job.

Many U.S. farm laborers are *migrants*—that is, they move into a region at harvesttime to help pick and process the crops. After the harvest is completed, the migrants move to another location.

Scientists and professionals of almost every type are employed in agriculture. For example, engineers develop improved methods of irrigation and more efficient farm machinery. Chemists produce safe and effective pesticides. Genetic engineers scientifically alter genetic material in order to produce desirable new traits in crops and livestock. Veterinarians protect the health of livestock.

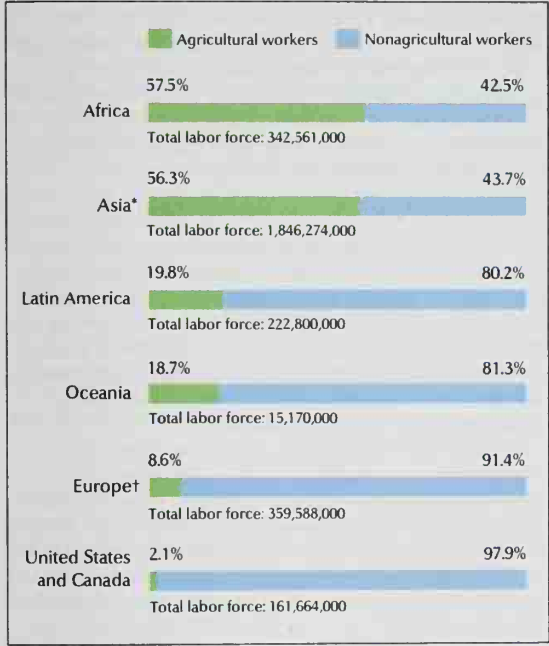
Business people involved in agriculture include bankers and loan officers. Buyers and brokers buy or negotiate the sale of crops and other agricultural products. Sales representatives sell agricultural goods, including machinery, seed, and feed.

Agricultural educators include high-school and vocational teachers, adult education specialists, and college faculty. They work with both young people and established agriculturists. Their jobs take them into traditional classroom settings or to farms, homes, and businesses. Agriculture educators teach new methods and ideas. They help farmers solve problems and devise management plans for wise use of resources.

Communications specialists who are knowledgeable about agriculture work in industry, education, and government. They include advertising representatives, editors, photographers, public relations specialists, and radio and television producers.

Canada

Canada's farmland covers about 7 percent of the country's total land area. Most of the country's farmland lies in the provinces that border the United States. About half of Canada's farmland is used to grow crops. The nation has about 250,000 farms. They average about 665 acres (270 hectares) in size.



Canada has two major farming regions. The larger one extends through the *Prairie Provinces*—Manitoba, Saskatchewan, and Alberta. The other region lies in southeastern Canada. The Prairie Provinces grow most of Canada's wheat, rapeseed, and barley. These provinces also produce about two-thirds of Canada's most valuable farm product—beef cattle. Farms in the southeast produce corn, dairy products, eggs, fruits, and vegetables.

Agriculture is organized and supported in Canada much as it is in the United States. Almost all the farms are privately owned. Most owners live and work on their farm, and many of them also hold a part-time job off the farm. Contract farming has become increasingly important. Many farmers belong to the Canadian Federation of Agriculture and the National Farmers Union. Both organizations work to advance the economic interests of Canada's farmers.

Agriculture Canada, an agency of the federal govern-

The agricultural labor force

The percentage of workers engaged in agriculture varies greatly throughout the world. In Asia and Africa, for example, about 60 percent of all workers are farmers. But farmers make up only about 2 percent of the total U.S. and Canadian labor force.

*Excluding Asian part of Russia.
†Including Asian part of Russia.
Figures are for 2000.
Sources: Food and Agriculture Organization of the United Nations, *World Book* estimates.

ment, is the country's chief agricultural agency. Each province also has its own department of agriculture.

Latin America

About 36 percent of the land in Latin America has been developed for farming. Much of the region lies in the tropics, and the tropical soils and climate are not well suited to many of the crops grown in cooler regions. The largest and most fertile farming areas are in Argentina, Paraguay, Uruguay, and southern Brazil.

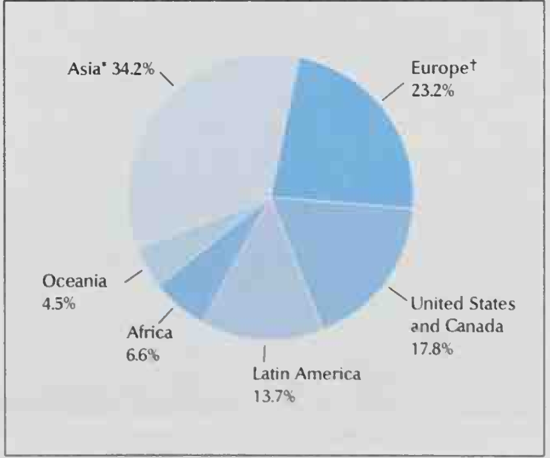
Most farmers in Latin America are subsistence farmers who live mainly on such crops as cassava, corn, dry beans, or potatoes. Commercial agriculture is also important in Latin America, however. Wealthy families own most of the region's commercial farms, and hired workers or tenant farmers supply the labor. But since the mid-1900's, many Latin American countries have begun land-reform programs. These programs have broken up many large estates and distributed the land among poor farmers.

Plantations in tropical Latin America grow most of the world's commercial supplies of bananas and coffee, about a third of the cocoa beans, and more than a fourth of the sugar cane. Large farms and ranches in Argentina and Brazil produce great quantities of food and other agricultural products. Both countries are among the world's top producers of beef cattle and soybeans. Brazil is also the world's leading producer of oranges, and Argentina is one of the chief wool-producing countries.

Europe

About 50 percent of the land in Europe, excluding Russia, is farmland. Most of this land is level and receives abundant rainfall. As a result, approximately 60 percent of Europe's farmland is used to grow crops. Farmers in most European countries use modern farming methods and equipment.

Russia has the largest land area of any country in the world. It ranks among the leading countries in area of farmland. But farmland makes up only about 15 percent of Russia's land. The majority of this farmland is in Europe. Most of the Asian part of Russia is too dry or has too short a growing season for farming. Some of the land in this region is suitable for raising livestock, however.



Western Europe has only about 4 percent of the world's farmland. Yet it is one of the most productive farming regions on the earth. Western European farms produce about 15 percent of the world's potatoes and wheat; about 20 percent of the eggs; about 30 percent of the milk and sugar beets; and about 35 percent of the barley. About 5 percent of all workers are employed in farming.

Agriculture in Western Europe is highly intensive. For example, most of the region's wheat is grown on small farms, and the farmers use large amounts of fertilizer on each unit of land. This intensive operation, combined with abundant rainfall, results in wheat yields that often average about 40 percent higher than those in the United States.

Western European farms are usually smaller and

Regional contributions to world crop production

This graph shows how much each major world region contributes to the world's crop output. Europe and the United States and Canada, taken together, account for 41 percent of the total production. But these regions have only about 3 percent of the world's farmers.

*Excluding Asian part of Russia. †Including Asian part of Russia.
Figures are for 2001. Source: Food and Agriculture Organization of the United Nations.

much more diversified than those in the United States and Canada. The typical farm covers only 35 to 40 acres (14 to 16 hectares). It is used to raise alfalfa, barley, potatoes, sugar beets, and wheat, as well as various kinds of livestock, such as cattle and hogs. Specialized farms produce great quantities of citrus fruits, grapes, milk, olives, poultry, and vegetables. Most Western European farms are privately owned.

About 16 percent of the workers in Eastern Europe work on farms. Farmers in Eastern Europe raise many of the same kinds of crops and livestock that Western European farmers raise. Most farms in Eastern Europe are owned by individual farmers or by companies. Some of these farms are much larger than those in Western Europe. Some are run as *joint-stock companies.* Managers and farmers on these farms are part owners who own stock in their farms. They buy their own equipment and decide what to grow and how to market their products. Farmers on joint-stock farms receive a share in profits and sometimes a small wage.

During the period of Communist rule, national governments owned most of the farmland in Eastern Europe. The main kinds of government-owned farms were *state farms* and *collective farms.* State farms were managed entirely by the government. The government paid wages and collected profits for the farm products. Collective farms were controlled by the government but managed partly by workers. Workers were paid wages and shared in profits.

In the late 1980's, non-Communist governments began to replace Communist governments in Eastern Europe. Many Eastern European countries passed laws allowing government-owned land to be distributed to or purchased by individual farmers. Some state-owned farms were broken up and sold to individual farmers or to agricultural companies.

Asia

Approximately 45 percent of the land in Asia is used for agriculture. Asia's farmland is extremely varied. It ranges from the high, dry plateaus of eastern Turkey to the hot, wet lowlands of Indonesia and Malaysia. The continent has more than 100 million farms. Most of these farms cover less than 1 acre (0.4 hectare) and are subsistence farms. Asia also has many large commercial farms that are operated with scientific methods.

The state owns most of the farms in the Communist countries of Asia. In Israel, most of the farms are cooperatively or collectively owned by the farmworkers (see **Israel** [Agriculture]). In other countries, the majority of farms are privately owned. In the past, much of the privately owned farmland in many Asian countries was worked by poor tenant farmers. The rents generally were so high that most tenant families barely survived. But since the mid-1900's, land reform programs in such countries as India and Pakistan have helped many tenant families gain title to their land.

About 60 percent of Asia's workers are farmers. Subsistence farmers grow such crops as cassava, rice, sweet potatoes, wheat, or yams. Many subsistence farmers also raise some livestock, usually a few chickens, goats, hogs, or sheep. Commercial farming is important in Asia's few industrial countries, such as Israel and Japan, and in China and Malaysia.

China is the world's leading producer of cotton and rice, and it ranks second only to the United States in the production of corn. Malaysia leads all other nations in the production of palm oil. Thailand, Indonesia, and Malaysia are all major producers of natural rubber. India produces more tea than any other country. The Philippines ranks as the leading producer of coconuts and coconut products. Plantations and many small farms throughout tropical Asia raise such export crops as bananas, coconut, sugar cane, and tea.

Australia and New Zealand

Farmland covers about 60 percent of Australia and more than 50 percent of New Zealand. In both countries, more than 90 percent of the farmland is pasture or relatively dry grazing land and is used mainly for raising cattle and sheep. Australia leads the world in wool production and is an important producer of beef, lamb, mutton, and dairy products. New Zealand also ranks high in wool, lamb, and mutton production.

Most of the cropland in Australia and New Zealand lies along the east coasts of both countries and in the southeastern and southwestern parts of Australia. Farms in these regions are operated in much the same way as farms in the major crop-growing areas of North America. Grains are the most important crops in both Australia and New Zealand. Australia produces large quantities of wheat.

About 5 percent of the workers in Australia and about 10 percent of the workers in New Zealand are employed in agriculture. Australian farms average nearly 5,000 acres (2,000 hectares) in size. New Zealand farms average about 750 acres (305 hectares). But the average farm size in both countries is much smaller if large livestock ranches are not included. Thus, the typical Australian farm, for example, covers about 335 acres (135 hectares). Most farms in both countries are privately owned commercial operations.

Africa

Deserts and tropical rain forests cover much of Africa. Only about a third of the land is used for farming. But about 60 percent of all workers are farmers. As in Latin America and Asia, subsistence agriculture is common in Africa. The main subsistence crops include bananas, barley, cassava, corn, sorghum, sweet potatoes, and yams.

Commercial agriculture centers in a few widely scattered areas. Irrigated farms along the coast of the Mediterranean Sea and in the Nile River Valley produce cotton, dates, grapes, olives, and wheat. Plantations and small farms in the tropics produce cocoa beans, coffee, cotton, palm kernels and oil, peanuts, sisal, tea, and tobacco.

Africa's richest farming country is South Africa. Unlike most other African countries, South Africa has large areas of fertile soil and a middle-latitude climate that is well suited to large-scale farming. Commercial farmers there are major producers of beef cattle, citrus fruits, corn, sheep, and sugar cane.

For hundreds of thousands of years, prehistoric people lived by hunting, fishing, and gathering wild plants. Then about 8000 B.C., people took the first steps toward agriculture. Some tribes discovered that plants can be grown from seeds. They also learned that certain animals could be tamed and then raised in captivity. These two discoveries marked the beginning of the *domestication* of plants and animals. Scholars believe that domestication began in the Middle East and then spread to surrounding areas. Later, people in other parts of the world independently learned how to domesticate plants and animals. Some time after the development of domestication, groups of people living in what are now Israel and Jordan began to depend chiefly on farming for food, even though they still hunted.

Agriculture developed independently in northern and southeastern Asia between 5000 and 4000 B.C. and in central Mexico by 1500 B.C. It spread to other parts of the world from these areas and from the Middle East. For more information on the beginning of agriculture, see **Prehistoric people** (The rise of agriculture); **Indian, American** (The first farmers).

Ancient times

People who farmed no longer had to travel in search of food. They could thus build permanent settlements. Some of these settlements developed into the first cities. Some of the cities, in turn, produced the world's first civilizations.

The Middle East. The first great civilizations arose in two regions of the Middle East. One region was the Nile River Valley of Egypt. The other was Mesopotamia, which lay northeast of Egypt between and around the Tigris and Euphrates rivers. Both regions had fertile soil, but neither received enough rain for crops to grow. Farmers discovered, however, that they could raise crops during most of the year if they used river water for irrigation. By about 3000 B.C., Egypt and Mesopotamia had developed the world's first large-scale irrigation systems. Also by about 3000 B.C., Egyptian and Mesopotamian farmers invented a plow that oxen could pull. Earlier farmers had pulled their plows by hand. The ox-drawn plows worked much better and faster and required much less human labor.

The large-scale irrigation projects and ox-drawn plows helped Egyptian and Mesopotamian farmers produce much more food than their families needed. The food surpluses enabled more and more people to give up farming and move to the cities. Classes of builders, craftworkers, merchants, and priests began to appear—and systems of writing were improved. These dramatic developments contributed greatly to the growth of civilization.

The Roman Empire began as a country of small farms on the Italian peninsula before 500 B.C. By the A.D. 200's, Rome had conquered much of Europe and the Middle East and the entire Mediterranean coast of Africa. As Rome grew, farms within the empire increased in size and became highly specialized. Most large farms specialized in raising wheat, which formed the basis of the Roman diet.

The Romans introduced into Europe the advanced farming techniques of the Middle East, such as the ox-drawn plow and methods of irrigation. The Romans also developed new farming methods. For example, they began the practice of leaving half of every field *fallow* (unplanted) each year. The fallow soil could store *nutrients* (nourishing substances) and moisture for a crop the following year. The Romans also developed systems of crop rotation. In one system, they used legumes, or pulses, as a rotation crop. Legumes enrich the soil with nitrogen, one of the chief nutrients that all crops need to grow. By building terraces, Roman farmers were able to grow such fruits as grapes and olives along the Mediterranean Sea's steep shoreline. In various parts of the empire, Roman engineers built long irrigation canals and huge structures to store grain.

The selective breeding of plants and livestock began in Europe during Roman times. For example, farmers in the part of Europe that is now the Netherlands produced the first specialized breed of dairy cattle, the Holstein, about 100 B.C.

The Middle Ages

During the A.D. 400's, barbarian tribes swept into the West Roman Empire. By the end of the 400's, the empire had fallen to the invaders, marking the start of the 1,000-year period known as the Middle Ages.

The barbarian invasions triggered civil wars throughout Europe. These wars, in turn, led to the collapse of Europe's economic system, including the use of money. A new economic system called *manorialism* gradually developed in many areas. Under this system, farms became part of large estates known as *manors.* The manors were controlled by rich lords. In most cases, they were worked by peasants known as *serfs.* The serfs supplied the lord of their manor with goods and services in return for use of the land. Serfs could not be denied use of the land as long as they fulfilled their duties to their lord. But they were not allowed to own land. See **Manorialism.**

European farmers invented a three-field system of crop rotation during the Middle Ages. In many areas, it

Detail of a clay seal (about 2900 B.C.) from Mesopotamia; the Louvre, Paris (Ronald Sheridan)

Agriculture began to develop in the Middle East about 10,000 years ago. Early farm products included grain.

replaced the Roman two-field system. Under the new system, farmland was divided into three fields rather than two. Farmers left one field fallow and raised a different crop in each of the two remaining fields. In this way, two-thirds of the land was farmed each year, instead of half of it.

During the 900's, a new and important kind of harness was introduced into Europe. Unlike earlier harnesses, it could be used to hitch a horse to a plow. A horse can pull a plow three or four times faster than an ox can. Thereafter, horses gradually replaced oxen as the chief source of power on many European farms.

European farmers continued to improve plants and livestock by selective breeding during the Middle Ages. Many special-purpose livestock breeds were developed. For example, a breed of dairy cow that gave especially rich milk was developed in northwestern Europe about 1100. This breed, called the *Guernsey,* is still a major source of milk used to make butter.

Manorialism had begun to die out in western Europe by the 1200's, as money again came into use for payment of goods and services. More and more peasants received wages for their work and paid rent for their land. But until the 1700's and 1800's, peasants still could not own land in most European countries.

Colonial agriculture

The European voyages of discovery that began in the 1400's greatly affected agriculture throughout the world. Crops and livestock that had been developed in isolated regions became widely known. Potatoes, for example, were unknown in Europe until Spanish explorers brought them from Peru in the 1500's.

American Indians had developed advanced systems of agriculture by the time the first European explorers arrived. In various parts of the Americas, Indian farmers grew cocoa beans, corn, peanuts, peppers, rubber trees, squash, sweet potatoes, tobacco, and tomatoes. Europeans first learned of these crops, and how best to grow them, from the Indians. The Europeans, in turn, brought their seeds, livestock, and farming tools and methods to the regions they explored and settled.

By the late 1600's, England, France, the Netherlands, Portugal, and Spain had colonies throughout the Americas. In tropical regions, the colonists established plantations that specialized in growing such crops as cocoa beans, coffee, and sugar for export. Labor was supplied by black slaves imported from Africa or by the native-born Indians, who were forced to work at low wages.

In most of England's North American colonies, however, the settlers started family farms. Each family had its own plot of land, which produced enough food and other products to meet the family's needs. Plantation agriculture became important only in England's Chesapeake Colonies (Maryland and Virginia) and Southern Colonies (North Carolina, South Carolina, and Georgia). By the mid-1700's, plantations in these colonies were growing rice, sugar cane, tobacco, and a dye-producing plant called *indigo.* By the time cotton became a major plantation crop in the late 1700's, the Chesapeake and Southern colonies had imported thousands of black Africans for slave labor.

Agriculture developed more slowly in the French colonies in what is now eastern Canada. The French, who controlled most of eastern Canada from the late 1500's until 1763, did little to encourage farming. Much of the land was owned by nobles or merchants called *seigneurs* (pronounced *seen YURZ).* The settlers themselves could not own land. But they could rent small plots from the seigneurs. By the mid-1600's, many French settlers had started small subsistence farms on rented land along the St. Lawrence River in Quebec. These farms, and similar ones in Nova Scotia and Prince Edward Island, remained almost the only farms in Canada until Britain gained control of the country in 1763. Settlers then began to clear the heavily forested lands of Ontario for farming. For more information about American colonial agriculture, see **Colonial life in America** (The economy); **Seigneurial system.** See also **Plantation; Slavery.**

Europeans established plantations in parts of Asia during the 1600's and after. But except on the planta-

The use of horses for farm work began in Europe during the Middle Ages and helped farmers increase their output.

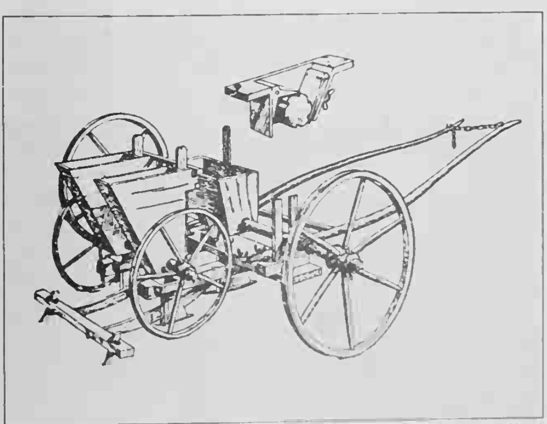
tions, few Asian farmers adopted European farming methods. Instead, they continued to use—and improve—the methods that had developed in their countries over hundreds of years. Rice growers, for example, continually improved the methods of irrigating their fields. As a result, such heavily populated countries as China, India, and Japan greatly increased their rice production from the 1600's through the 1800's. But in the 1600's, wealthy landowners throughout Asia began a system of tenant farming, which lasted almost unchanged until land reforms of the mid-1900's. The system kept the vast majority of Asian farmers in constant poverty.

The Agricultural Revolution

During the early 1700's, a great change in farming called the *Agricultural Revolution* began in Britain. The revolution resulted from a series of discoveries and inventions that made farming much more productive than ever before. By the mid-1800's, the Agricultural Revolution had spread throughout much of Europe and North America. One of the revolution's chief effects was the rapid growth of towns and cities in Europe and the United States during the 1800's. Because fewer people were needed to produce food, farm families by the thousands moved to the towns and cities.

The Agricultural Revolution was brought about mainly by three developments. They were (1) improved crop-growing methods; (2) advances in livestock breeding; and (3) the invention of new farm equipment.

Improved crop-growing methods. In the early 1700's, a retired English politician named Charles Townshend began to experiment with crop rotation. He found that turnips could be used as one of the four crops in a four-field rotation system. The other crops consisted of two grains, especially varieties of wheat; and a legume, such as alfalfa or clover. Each crop either added nutrients to the soil or absorbed different kinds and amounts of nutrients. Farmers therefore did not have to leave any land fallow, as in two- and three-field rotation systems.



Townshend's experiments did not become well known during his lifetime, except to earn him the nickname "Turnip" Townshend. But in the late 1700's, an English nobleman named Thomas Coke produced greatly increased yields using Townshend's system. Coke encouraged other farmers to adopt the method, and it soon became widely used in England. The system enabled farmers to grow crops on all their land each year, which made farmland much more productive. Both Townshend and Coke lived in the county of Norfolk, and so the four-field rotation system became known as the *Norfolk system.*

Before the development of the four-field system, farmers could not raise enough forage to feed livestock through the winter. Most livestock therefore had to be slaughtered in the fall, and the meat was preserved with salt. But the four-field system greatly increased the production of forage crops, especially turnips and clover. As a result, farmers could produce fresh meat throughout the year, not only during the months when livestock could be turned out to pasture.

Advances in livestock breeding. In the late 1700's, an English farmer named Robert Bakewell showed how livestock could be improved by intensively breeding animals with desirable traits. Bakewell produced improved breeds of cattle, horses, and sheep. He became best known for developing a breed of sheep that could be raised for meat as well as for wool. Earlier breeds of sheep were expensive to raise for meat because they fattened too slowly. As a result, most sheep were raised for wool only. But Bakewell's breed, called the *Leicester,* fattened quickly. It could therefore be raised for slaughter at a reasonable cost. The cost was so low, in fact, that mutton soon became the most popular meat in England.

The invention of new farm equipment. The first important inventor of the Agricultural Revolution was Jethro Tull, an English gentleman farmer. Tull lived during the late 1600's and early 1700's. But his inventions were not widely used until the late 1700's.

When Tull began his career, farmers still planted seed by sowing—that is, by hand scattering. To conserve seed and increase yields, inventors had tried to build a machine that would dig small *furrows* (grooves) in the soil

Detail of an engraving from *Horse-Hoeing Husbandry* (1731) by Jethro Tull; Historical Pictures Service

The first modern farm machine was a seed *drill,* or planter. It was invented by Jethro Tull of England about 1700.

Detail of an engraving (1869) in *Harper's Weekly* based on a drawing by William L. Sheppard (Library of Congress)

The cotton gin that Eli Whitney of the United States invented in 1793 saved workers the labor of cleaning cotton by hand.

and deposit seeds in them. About 1700, Tull built the first such seed *drill* that worked. Actually, it was the first successful farm machine with inner moving parts, and so it became the ancestor of all modern farm machinery.

One of the most important inventions of the Agricultural Revolution was the cotton gin that Eli Whitney of the United States built in 1793. Before Whitney's invention, farmers grew little cotton because of the difficulty of separating the fiber from the seeds. Whitney's gin simplified this work and so made large-scale production of cotton possible. During the early 1800's, cotton replaced tobacco as the leading plantation crop in the Southern United States.

During the late 1700's and early 1800's, inventors began to work on machines to harvest and process the ever-increasing amount of grain being produced by U.S. farmers. In 1834, Cyrus McCormick, an American inventor, patented the first successful harvesting machine, or reaper. Also in 1834, two American brothers, Hiram and John Pitts, patented a combined portable threshing machine and fanning mill. Their machine became the model for most modern threshers. During the early 1800's, inventors began work on developing a combined harvester and thresher, called a *combine*. But combines were not widely used until the early 1900's.

Equally important to increased grain production was a steel plow invented by John Deere, an Illinois blacksmith, in 1837. Earlier plows were made of cast iron and wood and did not easily turn the thick soil that covered much of the American Midwest. The soil would stick to the face of the plow and clog the *furrows* (narrow grooves). But the soil fell away easily from the steel face of Deere's plow, permitting it to cut a clean furrow.

Expansion in the United States

The invention of the reaper, the thresher, and the steel plow encouraged the development of farming in the well-watered eastern half of the American prairies. But farmers were not attracted to the dry prairie to the west—the region known as the Great Plains.

In 1862, Congress passed the Homestead Act to promote settlement of undeveloped, publicly owned land. The act granted 160 acres (65 hectares) of such land to anyone who lived on it for five years and developed it for farming. Or settlers could buy the land for $1.25 per acre after living on it for six months and making improvements on it. Congress also encouraged the building of railroads to speed settlement of undeveloped territories. The first railroad that linked the Great Plains with the eastern half of the United States was completed in the late 1860's.

From 1862 to 1900, about 500,000 families obtained land under the Homestead Act. Much of the land was in the Great Plains. The plains were covered with grass and so were ideal for grazing livestock. But because rainfall was light and undependable, crop yields were always low. To help solve this problem, Great Plains farmers developed a crop-growing method that was suited to the region's dry climate. This method, called *dryland farming,* generally requires that a field be left fallow every other year. The soil can thus store up moisture for a crop the following year.

Great Plains farmers found that wheat is better suited to dryland farming than are most other crops. The farmers soon began to produce plentiful wheat crops nearly every year. By the early 1900's, the plains had become one of the world's major wheat-producing regions.

In addition to the Homestead Act, Congress passed another bill in 1862 that greatly affected agriculture in the United States. This bill was the Morrill Act. It granted the states large areas of land to sell. The proceeds were to be invested and the income used to establish colleges of agriculture and the mechanical arts. The act thus led to the founding of many land-grant colleges. These schools, in turn, produced many of the remarkable advances in U.S. agriculture during the 1900's.

The development of modern agriculture

Since the 1800's, science and technology have helped make agriculture more and more productive. About 1850, for example, each U.S. farmer produced, on the average, enough food to feed 5 people. Today, each

An early gasoline-powered tractor did only light work. But it signaled the beginning of a new age of power for farming.

farmer produces enough to feed 78 people. Science and technology have contributed to the great increase in farm production in three main ways. They have (1) provided farmers with labor-saving technologies; (2) produced improved plant varieties and breeds of livestock; and (3) developed new agricultural chemicals.

Labor-saving technologies. Steam-powered tractors were developed in the mid-1800's, and some farmers in Europe and the United States began to use them. But the tractors were expensive, and they were difficult to operate. As a result, most farmers continued to use horses and mules to power farm machines.

The first successful gasoline-powered tractors were made in the United States in the early 1890's. However, they were not powerful enough for most farm work. By the early 1900's, engineers had designed models powerful enough to pull a plow. The first all-purpose tractors appeared in the 1920's. They could be used to power a variety of farm machinery, from combines to cotton pickers. The new tractors gradually replaced work animals and steam-powered machines on almost all U.S. farms. Today, there are millions of farm tractors in use throughout the world.

In Japan and several European countries, most farms had electric power service by the mid-1930's. The extension of electric service to rural areas of the United States was slow until the federal government established the Rural Electrification Administration (REA) in 1935. At that time, only about 10 percent of all U.S. farms had electric power. The REA helped expand service by granting low-interest loans for rural electric power development. By 1960, more than 97 percent of all farms in the United States had electric power.

Today, farmers use electric motors to run milking machines, irrigation pumps, and many other farm machines. Farmers also use electric power to operate electronic and automated equipment. This equipment includes devices that fill feeding troughs or collect and grade eggs automatically.

Many farmers use computers to aid in farm operations and to keep track of finances. They often use their computers to gain access to the Internet, the worldwide network of computers. Using the Internet, farmers may make use of data provided by agricultural colleges or other information centers. For example, they may use such information to determine the correct mixture of ingredients to use in livestock feed or to estimate the profit that can be expected from a particular crop.

Plant and livestock breeding. During the mid-1800's, an Austrian botanist and monk named Gregor Mendel discovered the principles of heredity. Mendel thus laid the groundwork for *genetics*—the science that explains how characteristics are inherited. The development of genetics has made it possible to breed plants and animals scientifically.

In the early 1900's, plant breeders in the United States developed a hybrid corn that produced unusually high yields. Various corn hybrids became commercially available in the 1920's. By the early 1960's, more than 95 percent of all U.S. corn acreage was planted with hybrid seed. Average corn yields in the United States increased dramatically. They nearly doubled between the early 1920's and the early 1960's, and they have continued to increase significantly since that time.

During the 1960's, scientists introduced varieties of wheat and rice that gave much higher yields than earlier varieties. The new varieties were intended mainly to help various poor nations, such as India and Mexico, increase their food supply. This effort proved so successful that it has been called the *Green Revolution.*

Livestock breeders have developed many improved lines since the early 1900's. They have also devised intensive selection techniques to speed genetic development. Nutrition specialists have developed better livestock feeds, and veterinarians have improved methods of health care. All these advances continue to make livestock more and more productive. For example, today's broiler chickens grow much faster than earlier breeds or lines, on much less feed. And the average annual milk production of cows in the United States is continually increasing.

Agricultural chemicals. Almost since the beginning of agriculture, farmers have used various substances to enrich the soil and to kill insect pests. For example, they have used wood ash and manure as fertilizers since prehistoric times. Arsenic, pyrethrum, and other natural poisons have long served as insecticides. Such substances were used because they worked. But little was known about why or how they worked.

Since the beginning of modern chemistry in the late 1700's, scientists have produced many kinds of synthetic chemicals for use in agriculture. These chemicals include (1) fertilizers; (2) insecticides; (3) *herbicides,* or weed killers; and (4) chemicals to control plant and animal diseases. All these chemicals have helped increase farm production dramatically. However, improper or excessive use of these chemicals can be hazardous and cause damage to the environment. In the United States, federal and state laws limit such practices and prohibit the use of chemicals that have been proved harmful.

Fertilizers. During the 1800's, scientists began to identify the chemicals that crops need to grow. They established, for example, that legumes are useful rotation crops because the plants incorporate atmospheric nitrogen into the soil. Scientists also identified other elements that crops need, such as phosphorus and potassium. Mixed fertilizers that contained the necessary elements soon became commercially available. But their use was often limited by high cost.

An economical commercial method of capturing atmospheric nitrogen was developed in 1909 by Fritz Haber, a German chemist. Nitrogen is such an important fertilizer element that the development of low-cost nitrogen greatly affected the use of fertilizer. Farmers throughout the world are using ever-increasing amounts of fertilizer. See **Fertilizer**.

Insecticides. In 1939, scientists in Switzerland developed a powerful chemical, called *DDT,* for use as an insecticide. By the early 1950's, farmers were using great quantities of DDT on their crops. However, scientists later discovered that although DDT killed insect pests, it also endangered other animal life. During the 1970's, the governments of many countries banned most uses of DDT. Today, most farmers use insecticides made of the

chemical compounds *organophosphate* and *carbamate*. For more information on methods of insect control, see **Insect** (Insect control); **Insecticide**.

Herbicides. Farmers have always had to fight against weeds. But until the mid-1900's, hand weeding, hoeing, and machine cultivating were almost the only methods farmers had to control weed growth. The first chemical herbicide, called *2,4-D,* was patented in the United States in 1945. It quickly became the most widely used herbicide. See **Weed** (Weed control).

Chemicals to control diseases. Like weed growth, plant and animal diseases have always been difficult and costly problems for farmers. Many plant diseases are caused by tiny organisms called *fungi.* Since the mid-1800's, scientists have developed a number of chemicals known as *fungicides* to help fight these diseases. Some plant diseases are caused by viruses or bacteria. Chemicals have also been developed to help control these diseases. In addition, scientists continually develop plant varieties that have greater resistance to disease. For further information on fungi and fungicides, see **Fungi** (The importance of fungi); **Fungicide**.

Most animal diseases are caused by bacteria or viruses. Some are controlled by vaccines. The great French scientist Louis Pasteur created the first livestock vaccines in the 1800's. They were developed against such diseases as anthrax and chicken cholera. Since 1900, chemists have introduced additional vaccines as well as antibiotics and other substances to help fight livestock diseases. See **Veterinary medicine** (On farms).

Recent developments. The demand for food throughout the world is constantly increasing. To help meet this demand, farmers have expanded their food output enormously. The largest increase in food demand has occurred in the nonindustrial, or *developing,* countries. Rapid population growth in these countries has been chiefly responsible for the increase. But most developing countries produce barely enough food to meet their present needs. And few can afford to import the additional supplies they need to feed their rapidly growing population. The developing countries therefore must expand their food production greatly or face a severe food shortage. Most developing countries, however, lack the resources that scientific farming requires.

Many industrial countries sponsor programs that provide farmers in developing countries with low-interest loans and technical training to help modernize their farm operations. The Food and Agriculture Organization (FAO)—an agency of the United Nations—helps coordinate the various national programs. The FAO also sponsors assistance projects of its own. See **Food supply**.

Throughout the 1970's, demand in other countries for U.S. farm products increased rapidly. As a result, many U.S. farmers borrowed large sums of money to expand production. But in the early 1980's, American farmers faced a severe farm debt crisis. Interest rates for borrowed money increased sharply, and worldwide demand for U.S. farm products decreased. This reduced demand led to lower prices for farm products. Thus, many farmers were unable to repay loans and prepare for a new growing season, and some had to sell their farms. Banks and other lenders *foreclosed* on loans that were not repaid—that is, they took over the farms. Many banks were forced out of business because they could not recover money they had loaned to the farmers.

In 1996, the U.S. government passed a law intended to eliminate or reduce price support payments that had been established in the 1930's for some crops. It made farm income for many crops more dependent on market prices. But high production and low farm prices in the late 1990's resulted in an increase in government payments to farmers. Larry D. Trede

Agriculture, Department of, is an executive department of the United States government. It works to maintain adequate supplies of farm products and to expand overseas markets for such products. It helps ensure reasonable incomes for farmers and reasonably priced farm products for consumers. The department also works to combat hunger in the United States and abroad and to improve the economy of rural America.

The secretary of agriculture, a member of the president's Cabinet, heads the department. The president appoints the secretary with the approval of the U.S. Senate.

Functions. The Department of Agriculture, also called the USDA, serves farmers and consumers in many ways. It works to safeguard the food supply by inspecting meat and poultry in slaughtering and processing plants. It grades meat, poultry, and dairy products to indicate their quality. It establishes standards of quality for grain exported from the United States and administers a nationwide system of grain inspection. The department's regulatory programs help protect animals and plants from pests and diseases.

The seal of the Department of Agriculture

The department runs food assistance programs to fight the problems of hunger and to improve the diet of Americans. These programs include the Food Stamp Program, which helps needy people purchase food; the National School Lunch Program; and a program to provide certain foods for pregnant women and for nursing mothers and their infants.

The USDA finances research in its own laboratories and in agricultural experiment stations at land-grant universities and other institutions. This research deals with such topics as plant and animal diseases, crop production, marketing of agricultural products, nutrition, pest control, and soil conservation. Together with state and county governments, the department sponsors a nationwide program of agricultural education.

*Has a separate biography in *World Book.*

The Department of Agriculture provides other services as well. It reports on crop production, crop prices, and farm operating costs. It gathers world agricultural data and provides technical assistance to help developing nations improve food production. The department's Forest Service manages national forests. The department also provides financial aid and other assistance to communities, businesses, and utilities in rural areas.

History. Congress established the Department of Agriculture in 1862. In 1889, it became a Cabinet-level department headed by a secretary of agriculture.

From the start, the department devoted much of its attention to developing and distributing information that would help increase agricultural production. Later, as improved farming methods led to larger crop yields, the department increased its emphasis on marketing farm products and supporting prices. In the 1960's, the USDA began to give more attention to expanding the agricultural markets at home and abroad and to ensuring an adequate diet for all Americans.

Agrimony, *AG ruh MOH nee,* is the common name for a group of about 18 species of woodland plants that grow in North America, Europe, Asia, and the Andes Mountains of South America. The hairy leaves are featherlike and consist of both small and large leaflets. The small yellow flowers occur in clusters on a long spike. The fruit is a cone-shaped bur with hooked bristles.

Kenneth R. Robertson

Scientific classification. Agrimony plants are in the rose family, Rosaceae. They are genus *Agrimonia.*

Agrippa, *uh GRIHP uh,* **Marcus** (63-12 B.C.), was a Roman general who was the chief adviser and military leader of Augustus, the first emperor of Rome. Agrippa was also a lifelong friend and loyal supporter of Augustus.

Agrippa rose to prominence during the civil wars that followed the assassination of the Roman leader Julius Caesar in 44 B.C. In these wars, Octavian, as the future Emperor Augustus was then known, struggled against a number of enemies for control of Rome. Agrippa became Octavian's best commander, both on land and sea. His most important victory was the Battle of Actium, fought off the west coast of Greece in 31 B.C. There, a fleet led by Agrippa defeated the forces of Mark Antony, co-ruler of Rome with Octavian, and Cleopatra, queen of Egypt. This victory cleared the way for Octavian to be named sole emperor of Rome, in 27 B.C.

Agrippa helped the new emperor in the reordering of Roman politics and society under one-person rule. When Augustus fell ill in 23 B.C., he gave Agrippa his seal ring. Augustus recovered, but the gift of the ring meant that Agrippa would have become emperor if Augustus had died. Agrippa married the emperor's daughter Julia in 21 B.C., another sign that he was the chosen successor. Agrippa held wide powers for the next 10 years but died before he could become emperor.

Arthur M. Eckstein

Agrippina the Younger, *AG ruh PY nuh* or *AG ruh PEE nuh* (A.D. 15-59), was one of the most powerful women in ancient Rome. She was the great-granddaughter of the emperor Augustus and sister of the emperor Caligula. She greatly influenced two other Roman emperors—her husband Claudius and her son Nero.

In A.D. 39, Caligula banished Agrippina from Rome for her part in a plot against him. She returned after her uncle Claudius became emperor in A.D. 41. She married Claudius in A.D. 49. The following year, she was honored by the founding of a Roman colony, Colonia Agrippinensis, at her birthplace in what is now Cologne, Germany. Agrippina persuaded Claudius to adopt Nero, her son by a previous marriage, as guardian of Claudius's son, Britannicus. Many Romans believed Agrippina poisoned Claudius in A.D. 54 so Nero could succeed to the throne. In the first year of Nero's reign, she had great political power. She retired from the imperial court after Britannicus died—probably by poison at Nero's order—in A.D. 55. Nero had Agrippina murdered four years later.

Judith P. Hallett

Agronomy, *uh GRAHN uh mee,* is a branch of agricultural science that deals with the study of crops and the soils in which they grow. Agronomists work to develop methods that will improve the use of the soil and increase the production of food and fiber crops. They conduct research in crop rotation, irrigation and drainage, plant breeding, molecular biology, soil classification, soil fertility, weed control, and other areas.

Agronomy involves selective breeding of plants to produce the best crops under various conditions. Plant breeding has increased crop yields and has improved the nutritional value of several crops, including corn, rice, soybeans, and wheat. It also has led to the development of new types of plants. For example, a hybrid grain called triticale was produced by crossbreeding rye and wheat. Triticale contains more usable protein than does either rye or wheat. See **Triticale**.

Agronomists study ways to make soils more productive. They classify soils and test them for substances vital for plant growth. In addition, agronomists develop methods to preserve the soil and to decrease the effects of erosion by wind and water. For example, a technique called contour plowing may be used to prevent soil erosion and conserve rainfall. Researchers in agronomy also seek ways to use the soil more effectively in solving other problems. Such problems include the disposal of wastes; water pollution; and the build-up in the soil of chemicals that are used to kill insects and weeds.

Most agronomists are researchers, consultants, or teachers. Many work for agricultural experiment stations, federal or state government agencies, industrial firms, universities, or international organizations.

Aguinaldo, *ah gee NAHL doh,* **Emilio,** *eh MEE lyoh* (1869-1964), was a leader in the fight for Philippine independence. In 1896, he took part in an unsuccessful revolt against Spanish rule. In 1898, he led a Filipino army against Spain in the Spanish-American War. In June of that year, the Filipinos set up a revolutionary government and made Aguinaldo president. He declared Philippine independence from Spain that same month. In December 1898, Spain gave up the Philippines to the United States for $20 million. In January 1899, Aguinaldo established the Philippine Republic, and his troops began fighting U.S. forces in February. United States forces captured him in March 1901. In April, Aguinaldo took an oath of allegiance to the United States and retired. He was born on March 23, 1869, near Cavite, Luzon. See also **Philippines** (History). Socorro L. Reyes

Ahmadabad, *AH muhd ah BAHD* (pop. 3,515,361. met. area pop. 4,519,278), is the largest city in Gujarat, a state in western India. It lies on the Sabarmati River in India's cotton-growing region (see **India** [political map]).

The city is a manufacturing and trade center for the nation's cotton textile industry. Ahmadabad's chemical industry produces drugs, dyes, pesticides, and plastics. Chemical plants have caused widespread air pollution.

Ahmadabad was named after Ahmad Shah I, the sultan of Gujarat who founded the city in 1411. The overcrowded, older section of the city lies on the east bank of the Sabarmati. Ahmadabad has many historic monuments as well as busy shopping areas. Weaving mills and other factories stand near this section. The west bank of the river includes many upper-class neighborhoods and Gujarat University. P. P. Karan

Ahura Mazda. See **Zoroastrianism.**

AID. See **Agency for International Development.**

AIDS is the final, life-threatening stage of infection with human immunodeficiency virus (HIV). AIDS stands for *a*cquired *i*mmuno*d*eficiency *s*yndrome. The name refers to the fact that HIV severely damages the immune system, the body's most important defense against disease. Cases of AIDS were first identified in 1981 in the United States, but researchers have detected HIV in a specimen collected in 1959 in central Africa. Millions of AIDS cases have been diagnosed worldwide.

How AIDS affects the body

Cause. AIDS is caused by two viruses that belong to a group called *retroviruses.* The first AIDS virus was isolated by researchers in France in 1983 and researchers in the United States in 1984. This virus became known as HIV-1. In 1985, scientists in France identified another closely related virus that also produces AIDS. This virus, named HIV-2, occurs mainly in west Africa. HIV-1 occurs throughout the world.

HIV infects certain white blood cells, including *T-helper cells* and *macrophages,* that play key roles in the immune system (see **Immune system** [Parts of the immune system]). The virus attaches to *CD4 receptor molecules* on the surface of these cells, which are often called *CD4 cells.* HIV enters CD4 cells and inserts its own genes into the cell's reproductive system. The cell then produces more HIV, which spreads to other CD4 cells. Eventually, infected cells die. The immune system produces millions of CD4 cells every day, but HIV destroys them as fast as they are produced.

Symptoms. People infected with HIV eventually develop symptoms that also may be caused by other, less serious conditions. With HIV infection, however, these symptoms are prolonged and often more severe. They include enlarged lymph glands, tiredness, fever, loss of appetite and weight, diarrhea, yeast infections of the mouth and vagina, and night sweats.

HIV commonly causes a severe "wasting syndrome," resulting in substantial weight loss, a general decline in health, and, in some cases, death. The virus often infects the brain and nervous system. There HIV may cause *dementia,* a condition characterized by sensory, thinking, or memory disorders.

Opportunistic illnesses. HIV makes infected people susceptible to infections and other conditions that do not normally occur or that are normally not serious. These illnesses are called *opportunistic* because they take advantage of the damaged immune system. With the onset of an opportunistic infection or one of several other severe illnesses or a marked decline in the number of CD4 cells, an HIV-infected person is considered to have AIDS.

There are many opportunistic illnesses that typically affect AIDS patients. In North America and Europe, *Pneumocystis carinii* pneumonia, yeast infections of the *esophagus* (tube that carries food to the stomach), cytomegalovirus retinitis, Kaposi's sarcoma, and tuberculosis are the most common. People with AIDS may contract several of these diseases.

Pneumocystis carinii pneumonia (PCP), which is an infection of the lungs, is a leading cause of death among AIDS patients. Yeast infections of the esophagus cause severe pain when swallowing and result in weight loss and dehydration. Cytomegalovirus retinitis is an eye infection that can cause blindness. Kaposi's sarcoma is a form of cancer that usually arises in the skin. The tumors may look like bruises, but they grow.

A major illness that defines AIDS in HIV-infected people is tuberculosis, a severe bacterial infection that usually affects the lungs. Throughout the 1900's, the number of cases of tuberculosis in the United States declined steadily. However, in the mid-1980's, doctors noticed a growing number of cases of tuberculosis in HIV patients. People with HIV are especially vulnerable to tuberculosis because of their damaged immune systems.

An HIV-infected person may develop AIDS from 2 to 15 or more years after becoming infected. In children born with HIV infection, this interval is usually shorter. Medical treatment can increase the interval by inhibiting the growth of HIV, preserving the immune system, and delaying the onset of opportunistic infections. An infected person can transmit the virus to another person whether or not symptoms are present. Infection with HIV appears to be lifelong in all who become infected.

How HIV is transmitted

Researchers have identified three ways in which HIV is transmitted: (1) sexual intercourse, (2) direct contact with infected blood, and (3) *perinatal* (transmission from an infected woman to her fetus or baby). The most common way of becoming infected is through sexual intercourse with an HIV-infected person. In the United States, sexual transmission of HIV has occurred mainly among homosexual and bisexual men, but it is becoming more

frequent among heterosexual men and women. HIV is transmitted through all forms of sexual intercourse, including genital, anal, and oral sex.

People who inject drugs into their bodies can be exposed to infected blood by sharing needles, syringes, or equipment used to prepare drugs for injection. In the past, transfusion and transplant recipients and people with hemophilia contracted the virus from the blood, blood components, tissues, or organs of infected donors. But screening and testing of donated blood and of potential organ donors have virtually eliminated this hazard. Health-care workers can become infected with HIV by coming into direct contact with infected blood. This infection may occur through injury with a needle or other sharp instrument used in treating an HIV-infected patient. A few patients became infected while receiving treatment from an HIV-infected American dentist and from a French surgeon.

An infected pregnant woman can transmit the AIDS virus to her fetus even if she has no symptoms. Transmission may also occur from an HIV-infected mother to her baby through breast-feeding.

Studies indicate that HIV is not transmitted through air, food, or water, or by insects. No known cases of AIDS have resulted from sharing eating utensils, bathrooms, locker rooms, living space, or classrooms.

Medical care for HIV infection and AIDS

Diagnosis. Tests for detecting evidence of HIV-1 in the blood became widely available in 1985. Tests for detecting HIV-2 became widely available in 1992. These HIV tests identify antibodies to the AIDS virus. Antibodies are proteins produced by certain white blood cells to react with specific viruses, bacteria, or foreign substances that enter the body. The presence of antibodies to HIV indicates infection with that virus. There is also an oral test for HIV-1 antibodies in mouth fluids.

Other tests directly measure the amount of HIV in the blood. These tests enable doctors to measure a patient's response to treatment, predict the future health of people with HIV, and estimate their survival time.

People with HIV infection are diagnosed as having AIDS when tests show that they have fewer than 200 CD4 cells per microliter (0.000001 liter) of blood or when they develop one or more opportunistic illnesses. All HIV-infected patients should have their health closely monitored by a doctor and get periodic blood tests to measure the levels of virus and CD4 cells in their blood.

Treatments have been developed, but no cure for HIV infection or AIDS has yet been found. Ever since AIDS was identified, scientists have worked to understand how HIV infects and damages human cells. In one important discovery, researchers learned that HIV uses an enzyme called *reverse transcriptase* to reproduce. Because this enzyme is not normally found in cells, scientists focused on developing drugs that block its action. These efforts led to development of a class of antiviral drugs called *reverse transcriptase inhibitors.* The first of these drugs, called zidovudine, commonly known as AZT, was licensed in the United States in 1987.

AZT and other reverse transcriptase inhibitors sometimes produce toxic side effects, including severe anemia that requires blood transfusions. HIV also develops resistance to these drugs when they are given singly. Doctors combine the drugs and vary the order in which they are given to improve their effectiveness.

In 1995 and 1996, the first three *protease inhibitors—indinavir, ritonavir,* and *saquinavir*—were approved for treating HIV. Other such medicines followed. These antiviral drugs block the action of *protease,* another HIV enzyme not found in human cells. Protease inhibitors block a later step in HIV reproduction than reverse transcriptase inhibitors do. Additional antiviral medicines may be developed with new ways of blocking the virus.

In 1996, several studies showed that certain combinations of antiviral drugs could decrease HIV in the blood to undetectable levels. Although HIV appears to persist inside CD4 cells, the studies raised hope that combination therapy can control reproduction of the virus. The research also raised hope for an eventual cure. But the drugs must be taken in large quantities for a long time, and HIV may develop resistance to them. Doctors need to determine which combinations of drugs are safest and most effective over the long term.

Physicians also prevent and treat opportunistic infections in AIDS patients. PCP can be prevented with specific antibiotics. Physicians use biological substances called *interferons* and chemotherapy to treat Kaposi's sarcoma. They use interferon plus antiviral medicines to treat hepatitis C (see **Interferon**). Researchers believe any eventual cure for AIDS must stop the growth of the

Stages of HIV infection

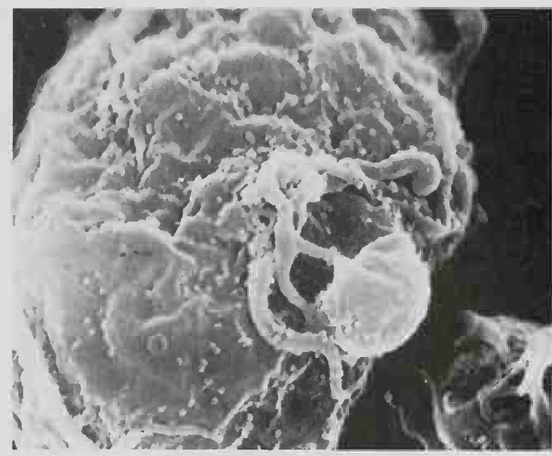
People infected with human immunodeficiency virus (HIV) go through three stages of infection. These stages are: (1) acute retroviral syndrome and asymptomatic period, (2) symptomatic HIV infection, and (3) AIDS. The length of time any person stays in each stage varies greatly and depends on many factors, including medical treatment. HIV can be transmitted during all stages of infection, even when no symptoms occur.

Acute retroviral syndrome and asymptomatic period. Most people get a flulike or mononucleosislike illness within 12 weeks after becoming infected with HIV. This illness, known as acute retroviral syndrome, usually goes away without treatment. From this point on, the infected person's blood tests positive for HIV antibodies even though symptoms usually do not develop for 2 to 15 years or more. During this early stage of infection, the patient maintains a near normal number of CD4 cells—that is, more than 500 CD4 cells per microliter of blood. CD4 cells are the white blood cells that are infected by HIV.

Symptomatic HIV infection. In this stage, a wide variety of mild or severe symptoms may appear. Common symptoms include tiredness, enlarged lymph glands, yeast infections, skin rashes, and dental disease. This stage of the infection may last from a few months to many years. During this time, the patient's CD4-cell count gradually declines, typically ranging between 500 to 200 CD4 cells per microliter of blood.

AIDS is characterized by severe damage to the immune system and such opportunistic infections as *Pneumocystis carinii* pneumonia and Kaposi's sarcoma. The progressive breakdown of the immune system eventually leads to death, usually within a few years. Most people with AIDS have fewer than 200 CD4 cells per microliter of blood, with most deaths occurring in patients with CD4-cell counts below 50.

virus, prevent opportunistic illnesses, and restore normal function to the immune system.



Prevention. To prevent transmission of HIV, a person must avoid sexual contact with anyone who is or might be infected with the virus. The most effective preventive strategies are to refrain from all sexual intimacy or restrict sexual intimacy to one uninfected person. Health authorities recommend that a condom be used every time sexual intercourse occurs with a person who is infected with HIV or whose infection status is unknown. Drug users should seek help to stop taking drugs and should never share hypodermic needles, syringes, or other injection equipment. Research has shown that AZT reduces the risk of transmission from an infected woman to her fetus or baby. Physicians administer AZT and other antiviral drugs to HIV-infected women during pregnancy and labor, and to their newborn babies. Doctors advise HIV-infected women not to breast-feed. Physicians, dentists, and other health-care workers now wear gloves, masks, and other protective clothing during many examinations and procedures.

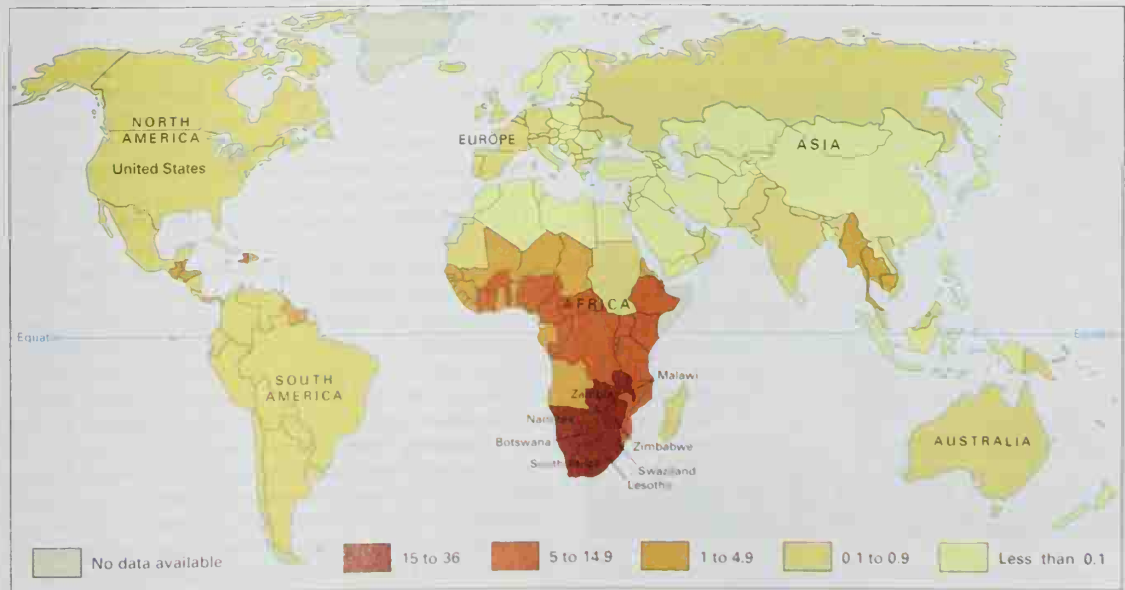
The tests to detect evidence of HIV-1 have been used to screen all blood donated in the United States since 1985. These tests have greatly increased the safety of transfusions. Screening for HIV-2 began in 1992.

Researchers are working to develop safe, effective, and economical vaccines against HIV infection. But even if HIV transmission ended, AIDS cases would still occur, since millions of people already have HIV. As a result, scientists are working to develop vaccines that would boost the immune systems of HIV-infected people.

Social issues

AIDS causes concern because it is a new, life-threatening disease, spread largely by sex and drugs, that mainly affects young adults. Some efforts to deal with AIDS or prevent HIV transmission have provoked controversy.

Centers for Disease Control and Prevention

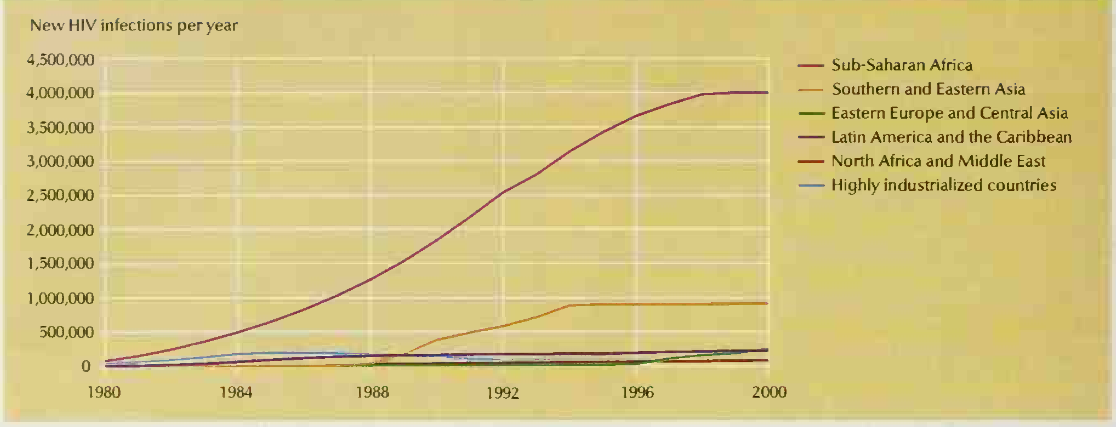


AIDS viruses reproduce in CD4 cells and circulate in the blood. In this electron micrograph of a white blood cell, AIDS viruses can be seen as the small white dots covering the cell's surface.

Education. Educating people about AIDS, both in schools and in the community, has become the chief approach to preventing infection. Some schools have set up health clinics that distribute condoms to students. However, some people oppose even classroom discussion of condom use because they believe it implies acceptance of sexual intimacy outside of marriage.

Preventing drug abuse and educating drug users about AIDS are important approaches to controlling HIV

Percentage of adults with HIV or AIDS



By 2000, an estimated 36 million people throughout the world had HIV or AIDS. The highest rates of infection were in central and southern Africa, where public health and education programs lacked resources to combat the epidemic.

WORLD BOOK map based on data from

Estimated number of new HIV infections by year worldwide

The number of people infected with HIV has risen dramatically, especially among people living in poverty. But efforts to control the spread of HIV have had some success. Education about HIV prevention has led to declines in the rate of new infection in some areas.

infection. Efforts to prevent HIV infection among drug users include health and sex education as well as needle and syringe exchange programs. But such programs have been criticized as seeming to imply acceptance of drug use.

In the United States, federal, state, and local governments have provided funds for AIDS education, treatment, and research. Public health clinics offer counseling and HIV-antibody testing to people who have symptoms or are at risk of infection. In addition, these clinics may privately and confidentially notify an infected person's sexual or needle-sharing partners of their risk. Once notified, they, too, can receive preventive counseling, testing, and medical services.

Public awareness. Many individuals and organizations, including community-based groups and the American Red Cross, have worked to increase public awareness of AIDS. They hope that greater awareness will result in more compassion and support for people with AIDS and adequate funding for AIDS prevention, research, and treatment. One project that has brought attention to the crisis is the AIDS quilt. Begun in 1986 by an organization called the NAMES Project, this quilt consists of thousands of individually designed panels, each of which memorializes a person who died of AIDS. The quilt has been displayed throughout the world.

Celebrities have helped raise public consciousness of AIDS. Many well-known entertainers, athletes, and others have participated in education and fund-raising efforts. The epidemic also has gained attention as a result of well-known people becoming infected with HIV or dying from AIDS. These people include actor Rock Hudson, who died of AIDS in 1985, and tennis champion Arthur Ashe, who died in 1993. Basketball star Magic Johnson announced he was infected with HIV in 1991, and Olympic diver Greg Louganis announced his infection in 1995.

The United Nations has designated December 1 each year as World AIDS Day. Public agencies and schools around the world sponsor education and prevention programs. Many individuals wear a red ribbon to show support for people with AIDS.

Discrimination. Some people infected with HIV have unjustly lost or been denied jobs, housing, medical care, and health insurance. Children with AIDS have been kept from attending school or playing on sports teams. To prevent discrimination, the federal government and many states include AIDS patients and people infected with HIV under laws protecting the rights of people with disabilities. Some states have strengthened laws that safeguard the confidentiality of medical records relating to HIV infection and AIDS.

Preventing discrimination against AIDS patients is important not only for moral reasons but also to help maintain public health. When people are not afraid of discrimination, they will more likely seek counseling and get tested for HIV. In many cases, these measures lead to less risky behavior and earlier diagnosis.

© J. L. Atlan, Sygma

The AIDS quilt memorializes people who have died of AIDS. The quilt is a moving symbol of the epidemic's human cost.

Providing medical care for the hundreds of thousands of people with HIV infection or with AIDS is expensive. Paying and planning for this care is a major health economics issue. The problem may be partly solved by increasing prevention efforts and by finding less costly antiviral medicines and alternatives to hospital care. Such alternatives include expanded home care services and hospice care.

Antiviral drugs are effective in prolonging the life of AIDS patients, but the cost of the drugs exceeds what nearly all individuals can pay. Patients in developing nations, who often have only limited access to medical care, cannot afford these medications. Experts view this issue, as well as the public health impact of AIDS itself, as a major challenge to social and economic progress in developing nations.

AIDS around the world

AIDS occurs in every nation. In Africa, India, and Southeast Asia, transmission of HIV has occurred mostly among heterosexual men and women. Heterosexual transmission of HIV, particularly among teens and young adults, has risen dramatically. HIV infection has become epidemic in many developing nations. In some parts of Africa, the epidemic has reached disastrous levels. According to the United Nations, 25 percent of the adults in some African countries are infected. The percentage is even higher in some large African cities. The number of young adults dying of AIDS in Africa has caused an overall decrease in life expectancy throughout the continent. Increasing numbers of people are infected in countries with growing drug abuse problems, such as the nations of central Europe, Russia, and China. Public health departments in many of these countries lack the resources to treat patients effectively or to control the epidemic through education.

History of AIDS

Scientists are not certain how, when, or where the AIDS virus evolved and first infected people. Researchers have shown that HIV-1 and HIV-2 are more closely related to simian immunodeficiency viruses, which infect monkeys and apes, than to each other. Thus, it has been suggested that HIV evolved from viruses that originally infected monkeys and apes in Africa and was somehow transmitted to people. In 1999, researchers in the United States found evidence that HIV-1 most likely originated in a population of chimpanzees in west Africa. The virus appears to have been transmitted to people who hunted, butchered, and consumed the chimpanzees for food. HIV was then transmitted sexually and perinatally to others, thus beginning the chains of transmission that have reached around the world.

Scientists believe HIV infection became widespread after significant social changes took place in Africa during the 1960's and 1970's. Large numbers of people moved from rural areas to cities, resulting in crowding, unemployment, and prostitution. These conditions brought about an increase in cases of sexually transmitted diseases, including AIDS. HIV may have been introduced into industrialized nations several times before transmission was sustained and became widespread.

AIDS was first identified as a "new" disease by physicians in Los Angeles and New York City in 1980 and 1981. The doctors recognized the condition as something new because all the patients were previously healthy, young homosexual men suffering from otherwise rare forms of cancer and pneumonia. The name *AIDS* was adopted in 1982. Scientists soon determined that AIDS occurred when the immune system became damaged, and that the agent that caused the damage was spread through sexual contact, shared drug needles, and infected blood transfusions.

Researchers developed tests to detect HIV infection. These tests have also been used to analyze stored tissues from several people who died from the late 1950's through the 1970's. Scientists have concluded that some of these people died from AIDS.

Cases of HIV infection reported worldwide rose dramatically during the 1980's and 1990's. By 2001, an estimated 36 million people throughout the world were living with HIV infection or AIDS. This number represents an increase of about 50 percent since 1991, when an estimated 24 million people were living with HIV or AIDS.

Efforts to control the spread of AIDS have had some success. For example, among homosexual men in the United States, HIV infection is spreading more slowly than it did in the early 1980's. This is due entirely to education about prevention and the resulting changes in sexual behavior, such as decreased numbers of sexual partners and increased use of condoms. HIV blood tests caused a gradual decline in transfusion-related cases in the late 1980's. The rate of AIDS in other groups rose, however, during the 1980's and 1990's. These groups include heterosexual men and women, people who inject drugs, and younger homosexual men.

Aiken, *AY kuhn,* **Conrad Potter** (1889-1973), was an American poet, novelist, and critic. He was a sympathetic ally of Ezra Pound, T. S. Eliot, and others who used new methods in poetry. Aiken's verse, however, is relatively conservative and deeply personal, and especially influenced by the Austrian psychiatrist Sigmund Freud. Aiken's central poetic concern was the problem of achieving personal identity in an unstable world of change. The greatest strength of his poetry is its musicality, which often overwhelms the poem's ideas. His *Selected Poems* won the 1930 Pulitzer Prize for poetry.

Aiken was born in Savannah, Georgia, but grew up in New Bedford, Massachusetts. In addition to several novels and collections of stories and essays, Aiken wrote *Ushant* (1952), an autobiographical fantasy. This work provides an eloquent account of the writer's development as an artist, despite personal setbacks and uncertainties. Aiken's *Collected Poems 1916-1970* was published in 1971. Bonnie Costello

Ailanthus, *ay LAN thuhs,* is a hardy tree that thrives in cities and places where other trees fail to grow. It is also called the *tree of heaven.* Although native to the forests of China, the tree grows throughout much of the world.

An ailanthus has smooth brown-gray bark and small greenish flowers. Male flowers give off an unpleasant odor. During spring and summer, the tree produces *compound leaves* (leaves with more than one blade) that smell like peanut butter when broken. In autumn, ailanthuses develop attractive, reddish-brown, winged fruits.

Because the ailanthus can live in most soils and many climates, people often call it a "weed tree." It resists injury from insects, diseases, and pollution. Seedlings carried by the wind sprout almost anywhere they land. Many ailanthuses grow at roadsides and forest edges. They also flourish in vacant city lots and sidewalk cracks. The tree develops rapidly. From seed, it may grow 8 feet (2.4 meters) in one year. A mature ailanthus stands about 60 feet (18 meters) tall. Norman L. Christensen, Jr.

Scientific classification. The ailanthus belongs to the quassia family, Simaroubaceae. It is *Ailanthus altissima.*

Ailey, *AY lee,* **Alvin** (1931-1989), was an American *choreographer* (creator of dances) and director of the Alvin Ailey American Dance Theater. Ailey's modern dances strongly reflected his Southern background. He composed many of them to black folk music and jazz. His works include *Revelations* (1960), *Mary Lou's Mass* (1971), and *Cry* (1971). He based *Survivors* (1986) on the antiapartheid movement in South Africa.

Ailey was born in Rogers, Texas. He studied and performed with the American choreographer Lester Horton. In 1958, Ailey formed his own dance company and in 1965, he retired from performing to devote himself to choreography. In addition to works created for his own company, Ailey composed dances for ballet, television, and opera. *Revelations,* an autobiography, was published in 1995, after his death. Katy Matheson

AIM. See American Indian Movement.

Ainu, *EYE noo,* are a group of people who may have been the first inhabitants of what is now Japan. There are about 15,000 Ainu. Most of the Ainu live on Hokkaido, Japan's northernmost main island. Until the mid-1900's, some Ainu also lived on Sakhalin and the Kuril Islands. Sakhalin is a part of Russia. Russia claims and occupies all the Kurils, but Japan claims the southernmost ones.

Scientists are uncertain about the ancestry of the Ainu. Some anthropologists think the Ainu are related to European peoples. Other anthropologists believe they are related to Asian peoples or Australian Aborigines, the original inhabitants of Australia. The Ainu language has not been clearly classified.

Through the centuries, many Ainu have intermarried with the Japanese and other neighboring peoples. The village was once the basic unit of Ainu society. Each village was headed by a leader and consisted of 5 to 30 one-room houses. Hunting, fishing, and gathering plants provided food for the community. The Ainu practiced a complicated set of religious ceremonies.

The Ainu have long been victims of discrimination. However, they have started a movement to achieve fair treatment in Japan. The Japanese government has begun a program of economic aid for the Ainu.

Air

Air is the mixture of gases that surrounds the earth. It is often called the *atmosphere.* Air covers the land and sea and extends far above the earth's surface. We cannot see, smell, or taste air. Yet it is as real as land or water. When the wind blows, it is the air you feel against your face. Wind is simply moving air. You can also see the effect of wind in drifting clouds, pounding waves, and trembling leaves. Moving air can turn windmills and blow large sailboats across the ocean.

Without air, there could be no life on the earth. All living things—animals and plants—need air to stay alive. You are breathing air now. You must breathe air, or you will die. People have lived more than a month without food and more than a week without water. But a person can live only a few minutes without air.

Air does much more than make it possible for us to breathe. Air shields the earth from certain harmful rays from the sun and other objects in outer space. At the same time, it traps the heat that comes from the sun. In this way, air helps keep the earth warm enough to support life. Air protects us from meteors, most of which burn up in the atmosphere before they can strike the earth's surface. Clouds that form in the air bring us water in the form of rain and snow. All living things must have water to live, just as they must have air.

We also need air to hear. Sound must travel through the air or some other substance. Most of the sounds we hear travel through the air. Thus, the world would be silent if there were no air. Air has weight. This weight enables balloons filled with a light gas or heated air to rise high above the earth because they are lighter than the air around them. Air moving past the wings of airplanes, birds, and insects enables them to fly.

The earth has plentiful air. But the quality of the air depends largely on the amount of industrial wastes and other *pollutants* (impurities) that people add to the atmosphere. Air pollution is a serious problem in most of the world's big cities. Polluted air harms our health. It also injures plants and animals, damages building materials, and even affects the weather. For a detailed discussion of the problem of air pollution, see the *World Book* article Air pollution. See also Environmental pollution (Air pollution).

What is air?

Air consists of a mixture of gases that extends from the earth's surface to outer space. The earth's gravity holds the air in place around the earth. The gases of the air move about freely among one another. As sunlight passes through the earth's atmosphere, it strikes molecules of the gases. The molecules scatter the sunlight, which is a mixture of all colors, in every direction. The sky appears blue because much more blue light is scattered than any other color. See Sky.

Many small particles of dust are suspended among the gases of the air. The air also carries tiny water drop-

The air around us is invisible. But we can feel the air when it pushes against us as gusts of wind. Wind is simply moving air. We can also tell that air has weight. This weight enables hot-air balloons to rise above the earth because they are lighter than the surrounding air.

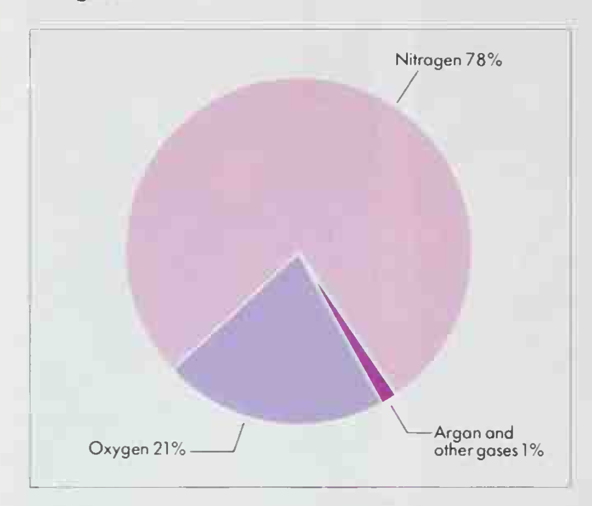
lets and ice crystals in the form of clouds. However, scientists do not consider the dust, water droplets, and ice crystals to be part of the air.

Gases of the air. The principal gases of the air are nitrogen and oxygen. Other gases include argon, water vapor, carbon dioxide, neon, helium, krypton, hydrogen, xenon, and ozone. The water vapor in the air is water in the form of an invisible gas. Nitrogen makes up about 78 percent of *dry air*—that is, air from which all water vapor has been removed. Oxygen accounts for about 21 percent of dry air. The remaining 1 percent consists chiefly of argon, with only extremely small amounts of the other gases.

Some gases of the atmosphere are particularly important. When we breathe, we take in oxygen from the air and give off carbon dioxide. Green plants take in carbon dioxide and give off oxygen in a food-making process called *photosynthesis* (see Photosynthesis). Oxygen from the air plays a part in such chemical processes as the rusting of iron and the formation of vinegar from cider. Most fuels must have oxygen to burn. Certain bacteria turn nitrogen that has passed into the soil from the atmosphere into chemicals that fertilize plants.

Water vapor and carbon dioxide are two of the gases in the air that help keep the earth warm. They prevent some of the surface heat created by sunlight from escaping back into space. This behavior of the gases is known as the *greenhouse effect* (see Greenhouse effect). Water vapor is also needed to produce rain and snow. Ozone, a form of oxygen, absorbs many of the sun's harmful *ultraviolet rays*, an invisible form of light (see Ultraviolet rays).

Moisture in the air takes the form of water vapor and tiny particles of water and ice. Vapor enters the atmosphere when water evaporates from oceans, lakes, rivers, and soil, or is given off from the leaves of plants. The amount of vapor in the air depends on location. For example, air near the equator usually contains much more vapor than air near the North and South poles. Air near sea level usually contains much more vapor than air several miles above sea level. The amount of water vapor in the air also depends on weather. Air usually contains more vapor on cloudy days than on clear days.



Warm air can hold much more water vapor than cold air. Scientists express the ability of air to hold water vapor in terms of *relative humidity*—the air's vapor content divided by its *vapor capacity*. Vapor capacity is often defined as the maximum amount of vapor the air could hold (see **Humidity**). According to this definition, air that is holding as much moisture as possible has a relative humidity of 100 percent. Air just above water surfaces, such as the ocean, often has a relative humidity near 100 percent. Air over dry surfaces, such as deserts, usually has a low relative humidity.

However, air in clouds can actually have a relative humidity greater than 100 percent; if air is cooled enough, its vapor capacity decreases. The excess vapor can then change to tiny water droplets or ice crystals in a process called *condensation*. The temperature at which water vapor begins to condense is called the *dew point*. Air cools as it rises, and clouds form when masses of moist air rise and cool below the dew point. The vapor in clouds condenses on tiny particles of matter.

Most droplets form when vapor condenses on tiny particles of sea salt or of a chemical compound such as ammonium sulfate or magnesium sulfate. Most ice crystals form when droplets containing other particles of dust freeze. After ice crystals form, vapor condenses more rapidly on them than on the droplets.

Every cloud consists of air filled with countless water droplets or ice crystals. Rain or snow is produced after the droplets or crystals become heavy enough to fall out

The gases of the air

Air consists chiefly of nitrogen and oxygen. They make up about 99 percent of *dry air*—air from which all water vapor has been removed. Argon and other gases account for about 1 percent.

of the clouds. Fog is a cloud near the earth's surface. See **Rain** (Formation of rain); **Snow**; **Fog**.

Particles in the air. Air always contains many tiny solid particles called *aerosols*. Most aerosols measure only about $\frac{1}{250,000}$ inch (0.1 micrometer) in diameter. They are therefore invisible, except when crowded together in extremely large numbers.

Many aerosols enter the air from active volcanoes, automobile exhaust, forest and brush fires, and factory smoke. The wind carries particles of dust and sand up from the ground into the atmosphere. Other aerosols include pollen from plants, salt from the oceans, ashes of meteoroids, and tiny living things called *microbes*. Aerosols are always being added to the air. But they do not remain in the atmosphere forever. Rain and snow wash out many aerosols, which is why air is fresher after it rains or snows. Other aerosols slowly fall to the earth.

Near the earth's surface, the number of aerosols in the air varies greatly from place to place. The air over the oceans contains about 30 million aerosols per cubic foot (1 billion per cubic meter). However, the polluted air over a large city may contain about 3 billion aerosols per cubic foot. Fewer aerosols float in the higher regions of the atmosphere.

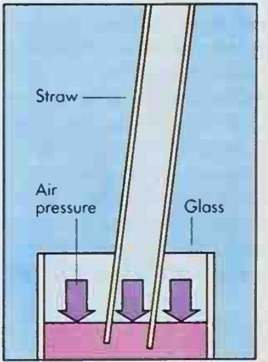
How air behaves

Weight and pressure. We do not usually notice the weight of air because air is much lighter than solids or liquids. At sea level, each cubic foot of air weighs only about 1 $\frac{1}{5}$ ounces, a measurement equivalent to about 1.2 kilogram per cubic meter. But the weight of all the air around the world is more than 5,700,000,000,000,000 tons (5,200,000,000,000,000 metric tons). The weight of the air pressing from the top of the atmosphere upon the layers of air below produces *air pressure*, also called *atmospheric pressure*. The air pressure at sea level averages 14.7 pounds per square inch (101.3 kilopascals). The air pressing down on your shoulders weighs about 1 ton (0.9 metric ton). You do not feel this weight because you are supported by equal air pressure on all sides.

An instrument called a *barometer* is used to measure air pressure. Barometers indicate air pressure in inches or millimeters of mercury or in units called *bars* and *millibars*. The bar is a unit of pressure in the metric system, equal to 100 kilopascals, and a millibar equals $\frac{1}{1,000}$ of a bar. On a barometer, the average atmospheric pressure at sea level is 29.92 inches (760 millimeters) of mercury, or 1,013 millibars. The atmospheric pressure changes a little each day with the weather. The pressure is usually lower on stormy, wet days than on clear, dry days. Thus, a falling reading on a barometer often indicates that a storm is approaching. See **Barometer**.

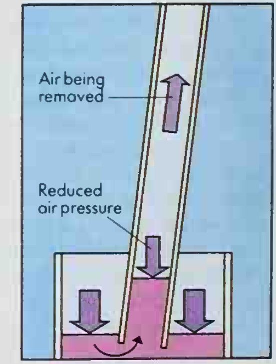
The upper atmosphere has less pressure than the air near the earth, simply because there is less air pressing down from above. When you ride up a tall building in a fast elevator, you can feel the air pressure changing. The pressure of the air inside the elevator decreases, but the air pressure inside your ears remains the same. This difference in pressure causes your eardrums to bulge outward slightly until some air finally forces its way out of your ears. You then feel your ears "pop."

We use the pressing force of air in various ways. When we suck a soft drink through a straw, for example, we do not pull the liquid up through the straw. Instead, by sucking on the straw, we remove some of the air from inside it. As a result, the air pressure inside the straw becomes less than the pressure of the air on the liquid outside the straw. The greater pressure of the air



How air pressure decreases with altitude

Altitude		Pressure	
In feet	In meters	In pounds per square inch	In kilopascals
50,000	15,000	1.8	12.1
40,000	12,000	2.8	19.4
30,000	9,000	4.5	30.8
20,000	6,000	6.8	47.2
10,000	3,000	10.2	70.1
Sea level	Sea level	14.7	101.3

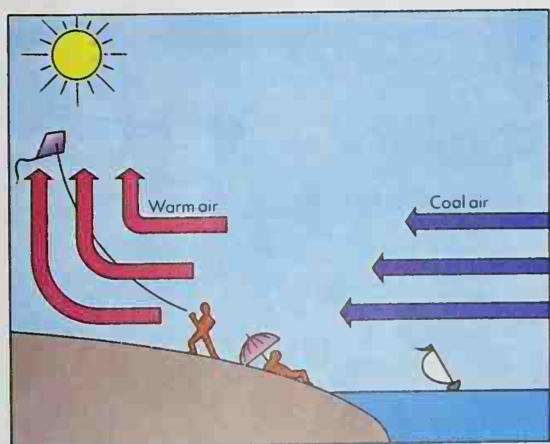


Air pressure

The weight of the air pressing down all around us produces *air pressure*. The diagrams here show one common way we use the force of the air—to drink through a straw. Sucking on the straw creates a partial vacuum inside it. The greater air pressure outside then pushes the liquid in the glass up through the straw.

WORLD BOOK illustrations by Oxford Illustrators Limited

Equal air pressure



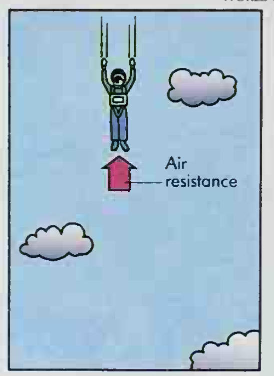
Unequal air pressure

outside then pushes the liquid in the glass up through the straw and into our mouths. Suction pumps and vacuum cleaners also work by means of air pressure (see **Pump; Vacuum cleaner**).

Air movement. Air moves across the surface of the earth in the form of wind. The sun causes the wind because it heats the earth's surface unevenly. Air above warm areas of the earth expands and becomes lighter. It then rises, creating an area of low pressure near the surface. Wind is produced when cooler, heavier air flows toward the low-pressure area, replacing the rising air. Wind often develops along an ocean shore during the day because land heats up more quickly than water does. The air over the shore is thus warmer than the air over the water. As the warm air over the shore rises, the cooler air from the sea moves inland and replaces it, producing a sea breeze. At night, the air over the shore becomes cooler than the air over the water. Thus, the wind direction reverses, and a breeze blows out to sea.

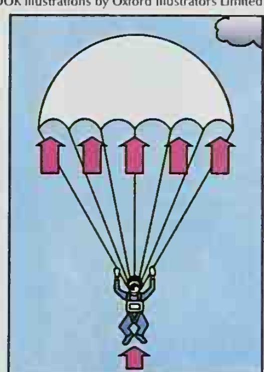
The warm air above the equator is usually rising. Cooler air from north and south of the equator blows in steadily, replacing the rising air. This movement of air creates two vast belts of winds called the *trade winds*. The trade winds do not blow straight toward the equator because of the earth's rotation. The trade winds north of the equator are twisted to the right of their original direction, or toward the southwest. The trade winds south of the equator are shifted to their left, or toward the northwest. This effect of the earth's rotation on the paths of winds is called the *Coriolis effect* or *Coriolis force*. The Coriolis effect also shifts the paths of four other great belts of winds that circle the earth. These winds are the *prevailing westerlies* and *polar easterlies* in each hemisphere north and south of the equator. See **Trade wind; Coriolis effect; Wind**.

Bands of fast-moving winds occur about 6 to 9 miles (10 to 15 kilometers) above the earth. These bands are known as *jet streams*. Winds in the core of a jet stream may exceed 200 miles (320 kilometers) per hour. Systems of swirling winds, called *cyclones* and *anticyclones*, also form in the air. The winds of cyclones swirl inward toward a center of low pressure. Anticyclones whirl outward around a center of high pressure. See **Jet stream; Weather** (Synoptic-scale systems).



WORLD BOOK illustration by Oxford Illustrators Limited

Air movement. Wind results from differences in the temperature of the air. For example, on a sunny day, the air above an ocean shore is warmer than the air over the water. The warmer air over the shore expands, becomes lighter, and rises. The cooler air from the sea moves in, producing a sea breeze.



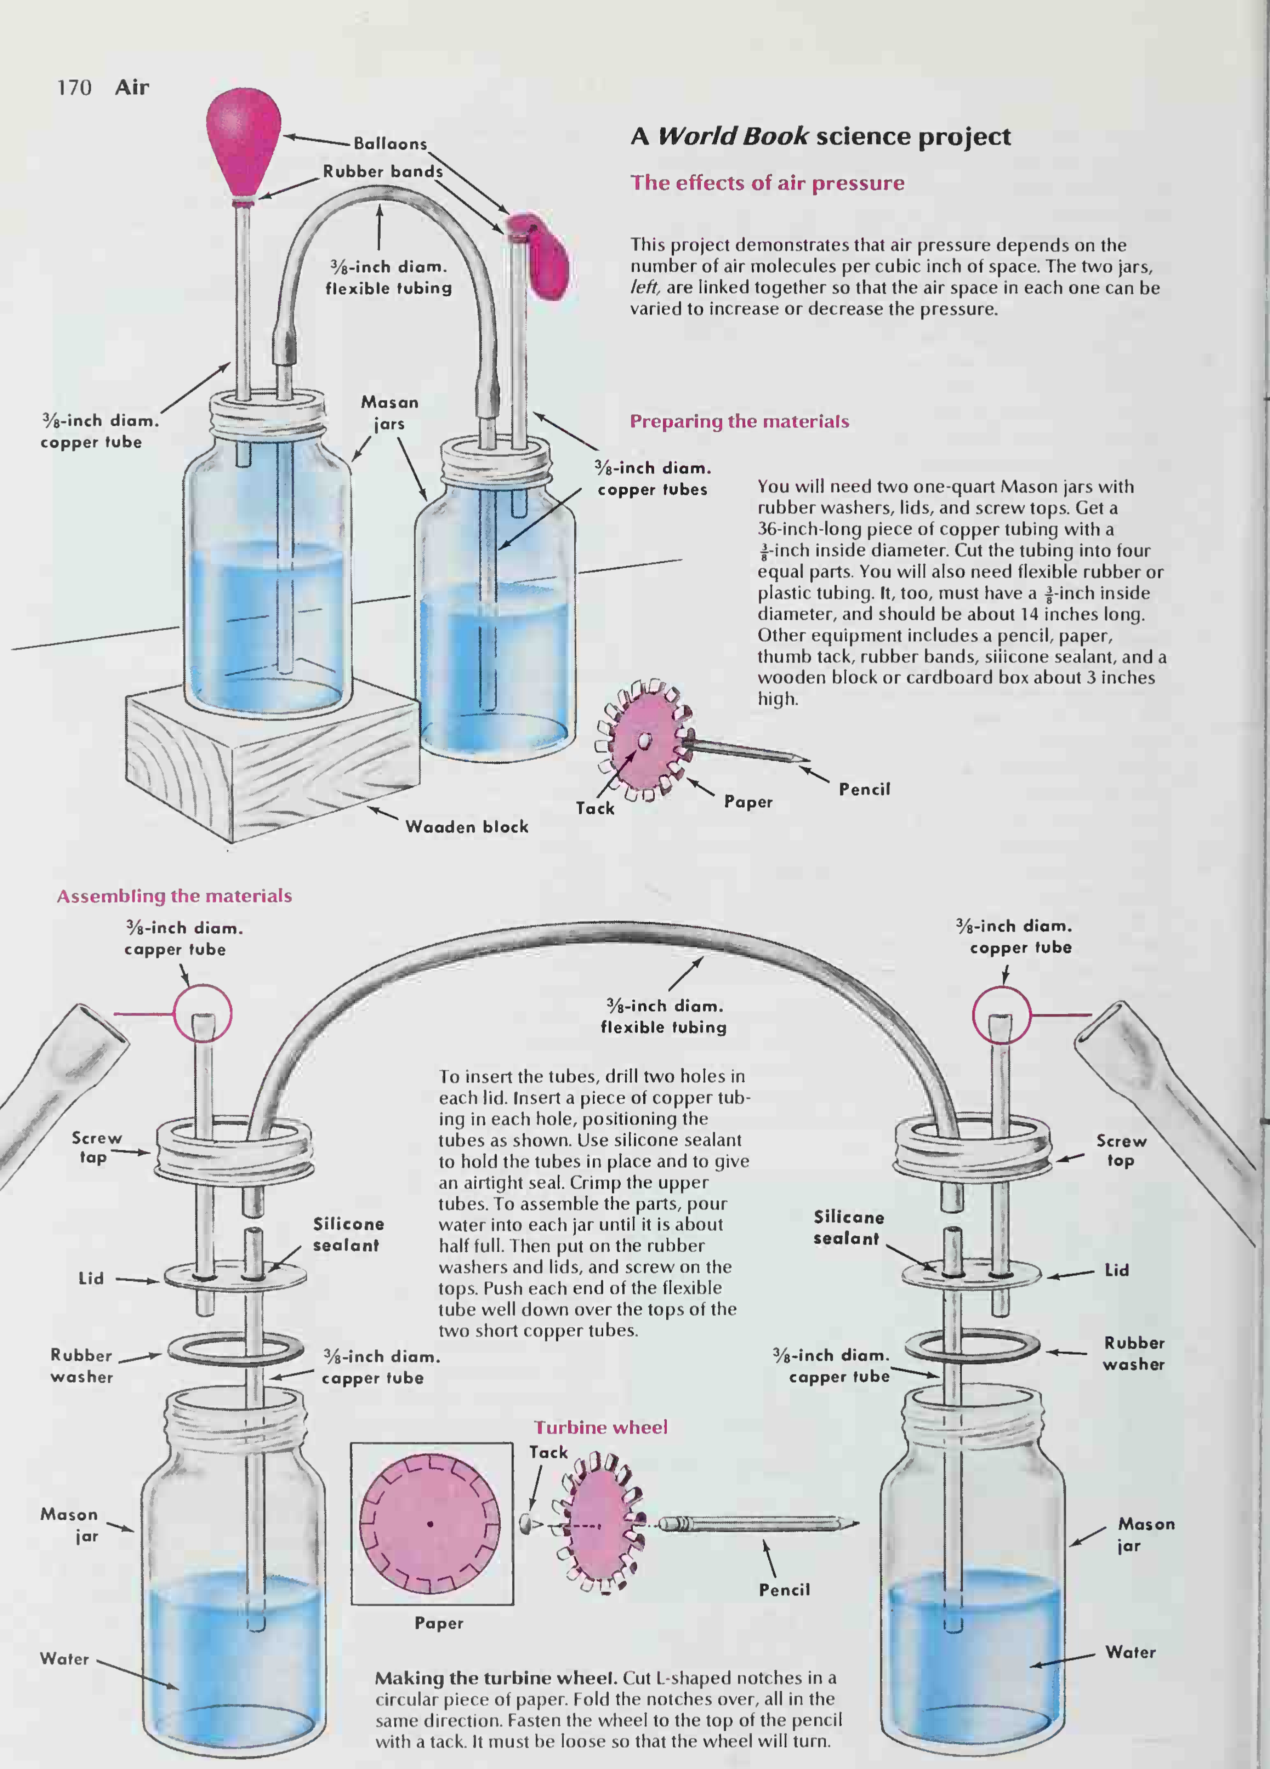
Air resistance

Air resists the motion of objects traveling through it. This resistance slows a parachute jumper's fall, *shown here*. The jumper meets minimum air resistance and falls rapidly until the parachute is opened. The greater resistance acting on the surface of the parachute enables the jumper to float safely to the ground.

WORLD BOOK illustrations by Oxford Illustrators Limited

Minimum resistance

Maximum resistance



Air resistance. Air resists the motion of objects traveling through it. This resistance occurs because moving objects rub against the atoms and molecules of the gases that make up the air. A piece of paper in the air floats slowly to the ground because of the air resistance acting on its surface. Air resistance slows down the speed of a parachute jumper's fall.

During the early days of aviation, airplanes flew slowly partly because such parts as the wing braces and landing wheels rubbed against the air. Aviation engineers found that they could reduce air resistance and thus increase the speed of a plane by streamlining its shape. They removed outside wing supports and installed landing wheels that could be pulled up into the plane. They found that even smoothing down rivet heads helped reduce air resistance. See **Aerodynamics**.

The faster objects move through the air, the more resistance they meet. For example, the faster you ride a bicycle, the stronger the air resistance against you will be. As you increase your speed, you can feel the air pushing harder and harder against you. Air resistance generates heat. Meteoroids move through the atmosphere at such great speeds that they encounter enormous air resistance and so become very hot. As a result, most meteoroids glow brightly, producing streaks of light known as *meteors*, and disintegrate before hitting the surface of the earth. Rockets traveling through the earth's atmosphere must be made of materials that can withstand the intense heat created by air resistance.

Air compression. Air can be pumped into steel cylinders or tanks until the air pressure is several hundred times greater than normal atmospheric pressure. Such air is called *compressed air*. When air is being compressed, the atoms and molecules of the air speed up. As their speed increases, the air gets warmer.

People use compressed air to inflate tires and air mat-

A *World Book* science project

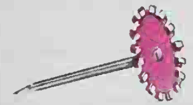
The effects of air pressure

This project demonstrates that air pressure depends on the number of air molecules per cubic inch of space. The two jars, *left,* are linked together so that the air space in each one can be varied to increase or decrease the pressure.

Preparing the materials

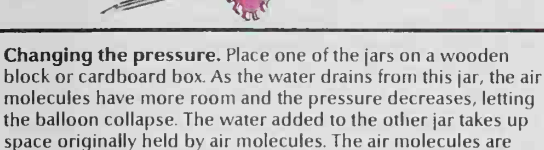
You will need two one-quart Mason jars with rubber washers, lids, and screw tops. Get a 36-inch-long piece of copper tubing with a $\frac{3}{8}$-inch inside diameter. Cut the tubing into four equal parts. You will also need flexible rubber or plastic tubing. It, too, must have a $\frac{3}{8}$-inch inside diameter, and should be about 14 inches long. Other equipment includes a pencil, paper, thumb tack, rubber bands, siiicone sealant, and a wooden block or cardboard box about 3 inches high.

Assembling the materials



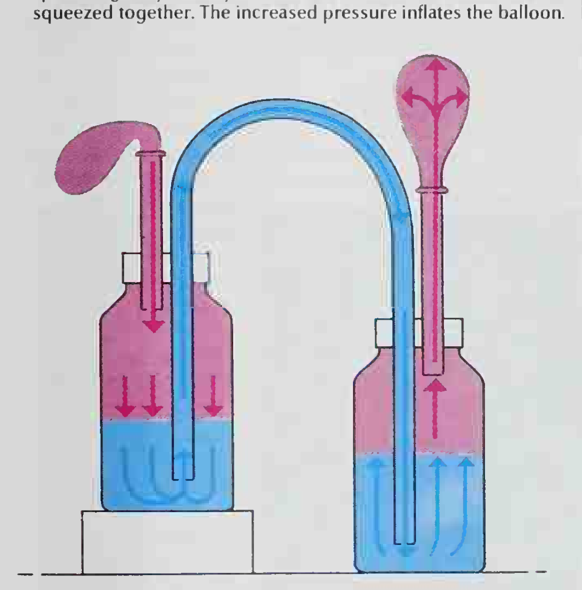
To insert the tubes, drill two holes in each lid. Insert a piece of copper tubing in each hole, positioning the tubes as shown. Use silicone sealant to hold the tubes in place and to give an airtight seal. Crimp the upper tubes. To assemble the parts, pour water into each jar until it is about half full. Then put on the rubber washers and lids, and screw on the tops. Push each end of the flexible tube well down over the tops of the two short copper tubes.

Turbine wheel

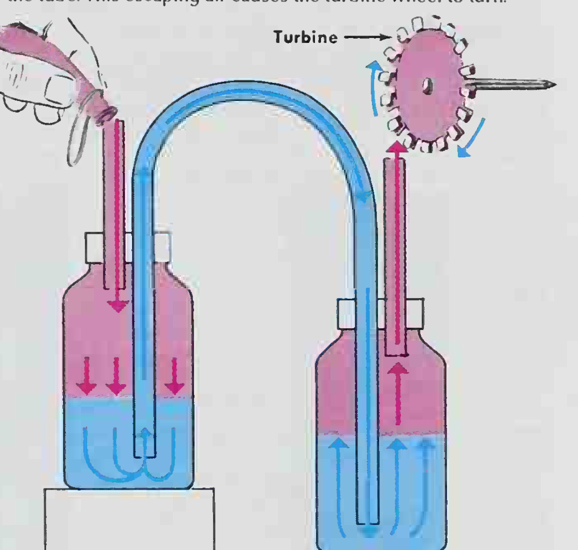


Making the turbine wheel. Cut L-shaped notches in a circular piece of paper. Fold the notches over, all in the same direction. Fasten the wheel to the top of the pencil with a tack. It must be loose so that the wheel will turn.

Demonstrating the project



To conduct a demonstration, slip a balloon over the top of one of the copper tubes with crimped ends. Fasten the balloon in place with a rubber band. Blow into the other tube until water flows from one jar to the other, completely filling the flexible tubing. Then cap the tube with the remaining balloon and twist a rubber band around it to hold it securely in place.



Changing the pressure. Place one of the jars on a wooden block or cardboard box. As the water drains from this jar, the air molecules have more room and the pressure decreases, letting the balloon collapse. The water added to the other jar takes up space originally held by air molecules. The air molecules are squeezed together. The increased pressure inflates the balloon.

Working the turbine. Leave one jar raised. Remove the balloon from the raised tube to allow more air into the jar so that the water will flow freely. Take the balloon off the other jar also, and hold the paper turbine wheel over the open tube. Water flowing into this jar increases the pressure, pushing air out of the tube. This escaping air causes the turbine wheel to turn.

How temperature affects air pressure

Balloons

Empty pop bottles

Pan of hot water

Pan of ice and water

WARM AIR EXPANDS

COOL AIR CONTRACTS

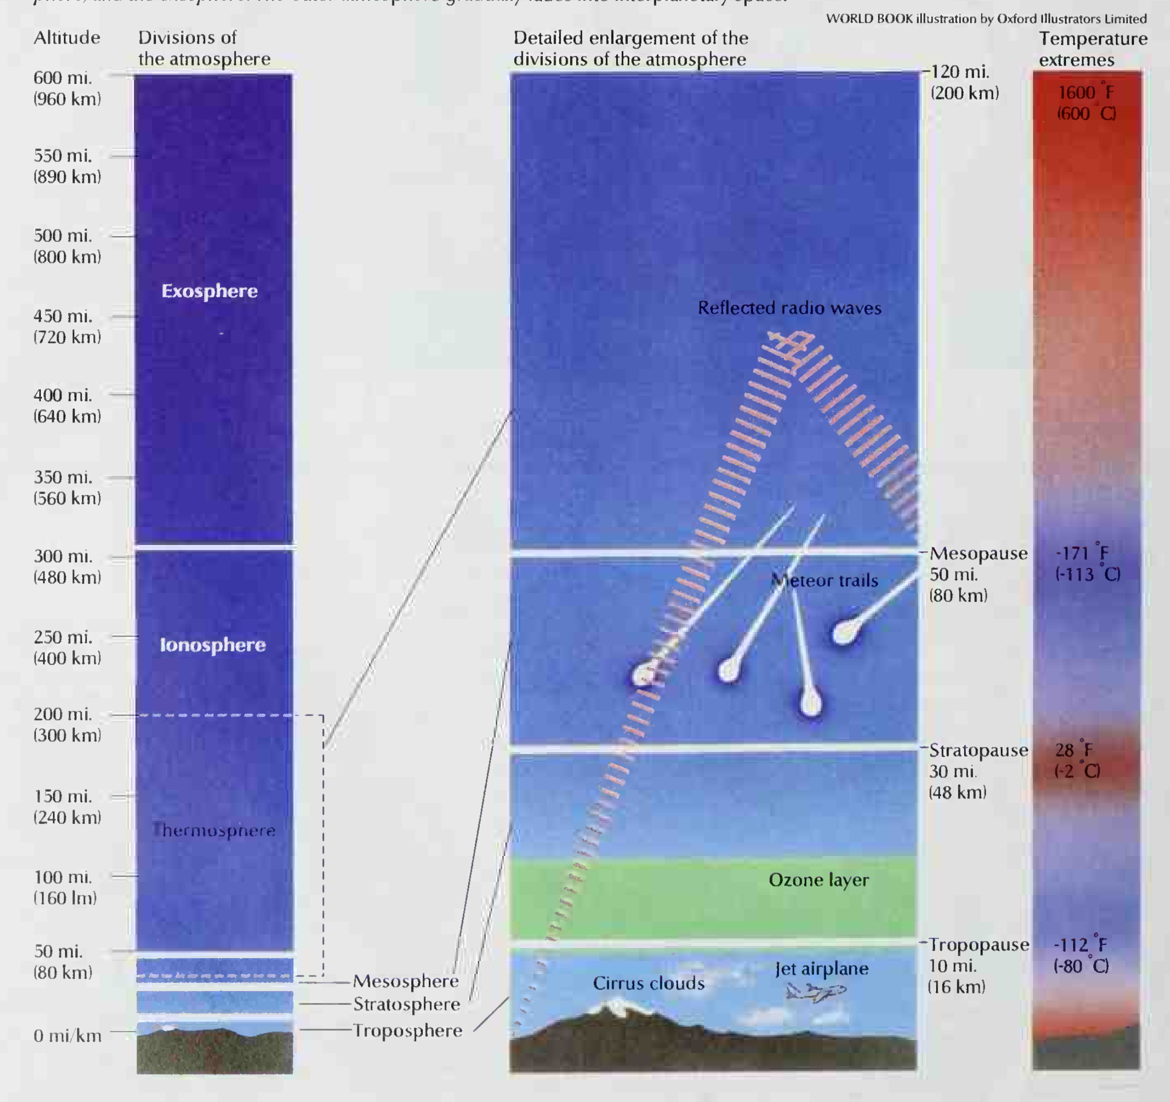
To use temperature to change air pressure, fasten a balloon on top of each of two pop bottles, and put the bottles in deep pans. Fill one pan with ice, and the other with hot water. The ice will cool the air in the bottle, causing the air to contract and deflate the balloon. The hot water will warm the air in the other bottle, causing the air to expand and inflate the balloon.

Illustrated by Art Lutz for WORLD BOOK

tresses. Scuba divers breathe from tanks of compressed air strapped to their backs. Submarines carry cylinders of air compressed to about $\frac{1}{200}$ its normal volume. A submarine dives as compartments called *ballast tanks* are flooded with water. It rises to the surface as the water is forced out of the ballast tanks by compressed air. Compressed air is also used to operate air brakes, certain insecticide and paint sprayers, and air hammers and other *pneumatic tools* (see **Pneumatic tool**).

Structure of the atmosphere

Scientists divide the earth's atmosphere into five layers according to differences in temperature. The layers, from lowest to highest altitude, are (1) the troposphere, (2) the stratosphere, (3) the mesosphere, (4) the thermosphere, and (5) the exosphere. The atmosphere becomes thinner with increasing height above the earth. The outer atmosphere gradually fades into space, where it meets the *solar wind*—that is, a continuous stream of charged particles from the sun. See **Solar wind**.



The troposphere is the layer of the atmosphere closest to the earth—the layer in which we live. The troposphere contains more than 75 percent of the earth's atmosphere. Nearly all the earth's weather conditions—including most clouds, rain, and snow—occur in this layer. Scientists forecast the weather by studying the troposphere. The troposphere also contains most of the aerosols and water vapor in the air. Jet streams blow in the upper part of the troposphere.

The temperature of the troposphere decreases about 3.5 °F for every 1,000 feet (6.5 °C for every 1,000 meters) of increase in altitude. The temperature stops decreas-

The layers of the atmosphere

Scientists divide the earth's atmosphere into five layers, according to differences in the temperature of the air. These layers are the *troposphere,* the *stratosphere,* the *mesosphere,* the *thermosphere,* and the *exosphere.* The outer atmosphere gradually fades into interplanetary space.

WORLD BOOK illustration by Oxford Illustrators Limited

ing at the *tropopause*, the upper boundary of the troposphere. The tropopause lies about 6 miles (10 kilometers) over the North and South poles and about 10 miles (16 kilometers) over the equator. At the tropopause, the air has become too thin to support life.

The troposphere is usually warmest near the earth's surface because sunlight that passes through the air heats the ground and seas. The ground and seas, in turn, warm the air directly above. Sometimes, especially at night and during the winter, the air near the earth's surface becomes cooler than the air above it. The temperature in a thin layer of the troposphere then increases with altitude. This abnormal situation is called a *temperature inversion*. The worst outbreaks of air pollution occur during temperature inversions because the cold air near the ground traps the pollutants, preventing them from rising and scattering. An inversion lasts until sunlight heats the air below or wind breaks up the overlying layer of warm air.

At the tropopause, the air is so cold that the clouds consist of ice crystals. The coldest part of the troposphere is at the tropopause over the equator. There, the air has risen so high that its temperature drops as low as −112 °F (−80 °C). The tropopause over the equator can be as much as 54 Fahrenheit degrees (30 Celsius degrees) colder than the tropopause over the poles.

The stratosphere extends from the tropopause to about 30 miles (48 kilometers) above the earth's surface. Very little moisture enters the stratosphere, so clouds are rare. Airline pilots prefer to fly in the stratosphere to avoid weather disturbances in the troposphere.

The stratosphere usually has a lower layer of nearly steady temperature and an upper layer in which temperature increases with altitude. The temperature of the lower layer is about −67 °F (−55 °C). The upper layer's temperature increases to about 28 °F (−2 °C) at the top of the stratosphere, called the *stratopause*. The stratosphere contains most of the atmosphere's ozone. Ozone heats the air by absorbing the sun's ultraviolet rays.

The mesosphere extends from the stratopause to about 50 miles (80 kilometers) above the earth. The temperature of the mesosphere decreases with altitude. The lowest temperatures in the earth's atmosphere occur at the top of the mesosphere, called the *mesopause*. At the mesopause over the poles, the air temperature drops as low as −171 °F (−113 °C) during the summer. Trails of hot gases left by meteors can be seen in the mesosphere. Extremely strong winds blow in this layer.

The thermosphere begins at the mesopause and extends to about 300 miles (480 kilometers) above the earth. The air in the thermosphere is extremely thin. More than 99.99 percent of the atmosphere lies below it. The chemical composition of the thermosphere differs from that of the lower layers. In the lower regions of the thermosphere, many of the oxygen molecules in the air are broken into oxygen atoms. The outer layer of the thermosphere consists chiefly of hydrogen and helium.

The thermosphere is completely exposed to the sun's ultraviolet radiation, which heats the thin air there to extremely high temperatures. Ordinarily, the temperature climbs rapidly from the mesopause to about 1100 °F (600 °C) at 120 miles (200 kilometers) above the earth and then levels off. But during *solar storms*, more radiation and particles strike the thermosphere (see **Sun** [Solar activity]). It then becomes much hotter, reaching a temperature as high as 3600 °F (2000 °C) at the top of the thermosphere, called the *thermopause*.

The lower part of the thermosphere and the upper part of the mesosphere are called the *ionosphere*. When radiation from the sun and from other sources in outer space strikes the air in this region, it *ionizes* (charges electrically) some of the atoms and molecules of the air. These charged atoms and molecules are called *ions*. The ionosphere plays an important part in radio communication. It reflects back to earth radio waves that would otherwise travel into space. See **Ionosphere**.

Light displays called *auroras* occur in the thermosphere. Auroras are produced when charged particles given off by the sun are captured by the earth's magnetic field. The particles strike the atmosphere in a ring around each of the earth's magnetic poles, releasing energy in the form of light. The display in the Northern Hemisphere is called the *aurora borealis* or the *northern lights* (see **Aurora**). The display in the Southern Hemisphere is the *aurora australis* or *southern lights*.

The exosphere begins at the thermopause and eventually merges with the solar wind. The exosphere has so little air that satellites and spacecraft orbiting the earth in the region encounter almost no resistance. The atoms and molecules of the air in the exosphere move extremely fast. Some travel so fast that they overcome the force of the earth's gravity and escape into space. The earth is thus slowly losing its atmosphere. However, the process will take billions of years before all the air around the earth disappears.

Origin of the atmosphere

Most scientists believe that the earth was formed approximately 4 $\frac{1}{2}$ billion years ago and probably did not then have an atmosphere. Slowly, gases that escaped from the developing earth began to accumulate around it. For example, numerous volcanoes on the young earth released such gases as ammonia, carbon dioxide, carbon monoxide, hydrogen, methane, nitrogen, sulfur dioxide, and water vapor. These volcanic gases made up a large part of the earth's earliest atmosphere.

Much of the water vapor from the volcanoes condensed, forming rivers, lakes, and oceans. Some of the other gases in the early atmosphere dissolved in the oceans or combined with rocks on the earth's surface. But most of the nitrogen stayed in the air. Additional gases, such as argon and xenon, were added by the decay of radioactive elements in the earth.

The earth's earliest atmosphere probably did not contain much oxygen. But after blue-green algae, also called *cyanobacteria,* and some simple green plants appeared in the oceans before 3 $\frac{1}{2}$ billion years ago, the amount of oxygen started to increase as a result of photosynthesis. As plants spread over the earth, more and more oxygen built up in the atmosphere. As oxygen increased, carbon dioxide in the atmosphere decreased. By about 400 million years ago, the air probably contained as much oxygen as it does today. See **Earth** (History of Earth).

Changes in the atmosphere

Human activity has caused small but important changes in the composition of the air. The amounts of many gases in the air, such as carbon dioxide, are in-

National Center for Atmospheric Research

A research balloon is inflated with helium in preparation for its launch, *shown here.* Scientific instruments aboard such balloons collect data about the earth's atmosphere.

creasing at significant rates. Carbon dioxide enters the atmosphere whenever coal, oil, or other fuels containing carbon are burned. Since the early to mid-1800's, the use of enormous amounts of these fuels has led to a 25 percent increase in the amount of carbon dioxide in the air. Levels of methane and nitrous oxide have more than doubled, and there were no *chlorofluorocarbons* (CFC's) in the atmosphere before 1930. CFC's are synthetic substances that were formerly used widely as refrigerants in air conditioners and refrigerators and as propellants in aerosol spray products.

Many scientists believe that the increases in the gases and the introduction of CFC's has strengthened the greenhouse effect. A strengthening of this effect would produce *global warming,* an increase in the average temperature of the earth's surface. See **Global warming.**

CFC's are also involved in the weakening of the protective layer of ozone in the stratosphere and troposphere. CFC's are harmless near the ground, but cause damage when they drift up into the stratosphere and troposphere. There, they break apart and release chlorine atoms. The chlorine reacts with the ozone, converting it into ordinary oxygen molecules. This conversion enables an increased amount of harmful ultraviolet radiation to reach the earth's surface. In 1990, the United States and most other industrialized countries agreed to stop production of most CFC's.

The study of air

Since ancient times, people have known that air is important to life. During the 400's B.C., Empedocles, a Greek philosopher, suggested that four elements—air, earth, fire, and water—combined in various proportions to make up all objects in the universe. Many other Greek scholars accepted this theory. In the 300's B.C., the Greek philosopher Aristotle wrote *Meteorology,* a collection of observations about the nature of air and the formation of weather.

Early philosophers and scientists could not test their theories about the air because they had no instruments to measure the air's properties. Around 1600, scientists began to use a type of thermometer to study air. Evangelista Torricelli, an Italian mathematician and physicist, invented the mercury barometer in 1643. In the mid-1600's, the Irish chemist Robert Boyle used the barometer to formulate the relationship between the volume of air and its pressure.

During the 1700's, scientists began to study atmospheric gases. Oxygen was discovered by the Swedish chemist Carl Scheele in the early 1770's and independently by the English chemist Joseph Priestley in 1774.

In 1777, Antoine Lavoisier, a French chemist, realized that oxygen in the air enables objects to burn. Daniel Rutherford, a Scottish physician, discovered nitrogen in 1772. In 1894, the Scottish chemist Sir William Ramsay and the English physicist Baron Rayleigh together isolated argon. By the late 1800's, scientists had found that the composition of the air is the same all over the earth.

During the early 1900's, Norwegian researchers headed by the physicist Vilhelm Bjerknes discovered that the movement of enormous bodies of air, called *air masses,* helps determine weather conditions. The researchers showed that when a warm air mass and a cold air mass meet, a zone of rapidly changing weather, which they called a *front,* develops. Their model of weather systems vastly improved the accuracy of weather forecasting.

Since the mid-1900's, scientists have made much progress in developing equipment for studying the atmosphere. Today, weather balloons, radars, satellites, and lasers monitor atmospheric conditions, air pollution levels, and changes in the composition of the air. Meteorologists can analyze the data supplied by these devices to prepare detailed weather forecasts.

In December 1999, the National Aeronautics and Space Administration (NASA) launched Terra, the first satellite of an extensive program known as the Earth Observing System. Terra can monitor 16 factors that determine climate, including aerosols, air temperature, clouds, and water vapor. Stanley David Gedzelman

Air, Liquid. See Liquid air.

Air bag is an inflatable automobile safety device that helps protect a driver or passenger in a collision. An air bag is most effective used with lap and shoulder belts.

An air bag system consists of one or more cloth air bags, an inflator, and devices called *sensors.* The sensors can detect a sudden slowdown, which would occur in a frontal collision, or the jarring force of a side impact. Sensors to detect frontal collisions are usually mounted at the front of the vehicle and in the passenger compartment. Those that detect side collisions are usually in the door and in the center pillar at the side of the vehicle. The sensors run on energy from the vehicle's battery or from a computerized control unit, a device that also monitors the system for malfunctions.

Air bags are designed to inflate in frontal or front-angle impacts in which the automobile strikes an immovable object at more than about 10 miles (16 kilometers) per hour or another car at about twice that speed. A side-impact air bag can be triggered by less impact.

After an impact, sensors send an electric current to an igniter system or, in some cases, to the computerized control unit. This unit evaluates the situation and then sends an electrical impulse to the igniter system. The electric current heats a *filament* (wire), which in turn ignites a capsule. This ignition capsule supplies the heat to ignite gas-generating pellets.

In most systems, the pellets are made of sodium azide, which produces nitrogen gas when it burns. The gas expands quickly and inflates the air bag, which then breaks through a plastic cover in the steering wheel, the dashboard, or a door panel. The whole process takes about 0.1 second from the moment a frontal impact is detected, and even less time in the event of a side impact. The air bag starts to deflate immediately, venting the harmless gas through holes in the back of the bag or through the fabric itself.

Safety experts have raised concerns that air bags can injure children, pregnant women, and adults of below-average height by hitting them on the head or neck. Automobile manufacturers are developing systems that can adjust the position and inflation speed of an air bag based on the position and size of the person in the seat. The United States National Highway Traffic Safety Commission recommends placing all children 12 years old and younger in the back seat. William H. Haverdink

General Motors

A cloth air bag helps protect the driver in a head-on collision. The bag inflates within a fraction of a second after a frontal or front-angle impact.

Air brake. See Brake (Air brakes).

Air cleaner is a device that removes *contaminants* (impurities) from a stream of gas or air. Solid contaminants include dust, lint, smoke, and pollens. Liquid contaminants include mist and fog. Other contaminants come in the form of vapors and gases.

Uses. Air cleaners serve many different purposes. In homes, they improve the cleanliness of the air and reduce housekeeping time. Special types of air cleaners help to eliminate pollens and dust, and thereby bring relief to individuals who suffer from hay fever and other allergies. Department stores may use air cleaners to keep merchandise clean, and to reduce fire hazard by collecting lint or other burnable material that may be deposited in the ventilation system. Hospitals use air cleaners to reduce or eliminate the spread of infection.

Without air cleaners, many industries could not operate efficiently. For example, food processing and electronic equipment manufacturing require relatively dust-free air. Air cleaners can lower expense by recirculating conditioned air from heating and air-conditioning systems. Air-cleaning systems also keep exhausted contaminants from reentering the factory. Sometimes industrial dust or odors must be removed to keep the air from harming people in the area nearby. Air cleaners also protect internal-combustion engines and other machinery from excessive wear.

Types of air cleaners. The type of air cleaner used depends on the size and the amount of particles to be removed and on the characteristics of the contaminant. Cost is also important because some air-cleaning systems cost more to buy, operate, and maintain than others. Air cleaners are classified according to their principle of operation. The chief types of air cleaners are (1) filtration, (2) electrostatic precipitator, and (3) inertial.

Filtration air cleaners use a dry, uncoated filter made of such materials as wool felt, cotton batting, or cellu-

lose fiber. They come in both cleanable and throwaway types. Dry filters can hold large amounts of lint. But large accumulations can clog the filter pores, slowing the air flow through the filter and disturbing effectiveness. The most familiar dry filters are those used in the air cleaners of automobiles and in the heating and cooling systems of homes.

Special dry filters, called *HEPA, ultra,* or *absolute,* have an efficiency as high as 99 percent. They contain such material as pleated cellulose-fiber paper, deep sand beds, a combination of fiberglass and wool, or a compressed fiberglass. Slightly less efficient versions used in the home remove pollen, smoke, and tiny dust particles from the air. These filters actually increase in efficiency as they accumulate contaminants, until they reach their maximum effectiveness.

Electrostatic precipitators are among the most important air cleaners in use today because they run so efficiently and have so many different uses. They are especially useful for removing particles of dust and smoke, but they also remove bacteria and pollen.

Some types of electrostatic precipitators are designed only for cleaning ventilating air in such places as homes, offices, hospitals, and stores. Other types of electrostatic precipitators are widely used in industry to clean air and gas.

An electrostatic precipitator consists of an *ionizer,* through which air passes; a *cell,* or *collector,* which removes the contaminant; and a *power pack,* which provides direct-current electric energy. A fan blows the contaminated air past a number of small, electrically charged wires in the ionizer. In most electrostatic precipitators, the particles receive a positive electric charge. The charged particles are said to be ionized (see Ion). The particles then pass to the cell, which consists of a series of metal plates. Some of the plates carry a positive charge, but others carry a negative charge. The positively charged dust particles are attracted to the negatively charged metal plates because opposite charges attract one another, and like charges repel each other. The dust particles stick to the metal plates until the plates are cleaned, usually by washing them in detergent and water.

Inertial air cleaners use the principle of centrifugal force (see Centrifugal force). They change the direction of the air flow so that dirt particles are thrown out of the air stream. Inertial air cleaners are primarily used in industry for the continuous removal of dust, granular material, and other contaminants.

Other types of air cleaners. Absorber cleaners use simple absorbing agents, such as water or alkali. Absorber cleaners are used to remove soluble gases in various industrial processes. In some industries, certain combustible gases or vapors become dangerous. *Combustion* cleaners burn these gases at a high temperature and ensure safety. They also burn gases or vapors that have an unpleasant odor. *Adsorption* cleaners are used to recover solvents where large amounts of solvent vapor are given off. The adsorbing material is powdered charcoal, silica gel, or some other substance that does not change physically or mechanically during the adsorption process. Some *scrubber* cleaners wash the air with an air washer, such as a stream of steam. Scrubber cleaners also absorb gases or collect solid particles with wet filters or containers full of ceramic material.

Another type of air cleaner, the *viscous-impingement* cleaner, was once commonly used in automobiles. Air entering the carburetor was usually forced through a metal mesh screen wetted with oil. It then passed through a pool of oil to help collect any remaining dust.

Air compressor is any device used to compress air. A common type works on the same principle as a pump. It has a piston that moves back and forth within a hollow cylinder, compressing the air and forcing it into a closed chamber. Pipes or hoses connected to the chamber channel the air to tools and other devices that run on compressed air.

Air compressors do many important jobs. Trains and heavy road vehicles have air compressors that supply the air used to power their brakes (see Brake [Air brakes]).

Air compressors also provide the air that runs *pneumatic* (air-powered) tools in manufacturing plants, construction sites, and home workshops (see Pneumatic tool). Such compressors may be driven by electric motors or by gasoline or diesel engines. Compact compressors powered by electric motors are used in the home to operate paint sprayers. *Rotary* (fan-type) compressors are used in gas turbines, jet engines, and other devices. Evan Powell

See also Free-piston engine; Pump (Axial-flow pumps); Turbine (Gas turbines; diagram).

Air conditioning controls the temperature, moisture, cleanliness, and movement of indoor air. It cools the air when the weather is hot. It warms the air when the weather is cold. Comfort depends partly on humidity, and air conditioning removes moisture from the air or adds it as needed. Removing dirt and dust from air makes the air more healthful. By controlling air movement, air conditioning brings fresh air into a room and pushes out stale air. In all these ways, air conditioning provides air that makes people comfortable at work, at play, and while sleeping.

How we use air conditioning

For comfort. When the weather is hot, most people enjoy eating in cool, air-conditioned restaurants. They sleep better in air-conditioned bedrooms. Airplanes, trains, ships, buses, and automobiles that are air conditioned make traveling more pleasant. Air conditioning helps keep homes clean by taking dirt from the air. It often relieves the discomfort of hay-fever victims, because it removes pollen from the air. Air-conditioned hospitals protect the health and improve the comfort of patients and hospital staffs.

During cold weather, air conditioning performs much the same services. It supplies clean, moist air that is warmed to the most comfortable temperatures for working and sleeping.

In business and industry, air conditioning improves the efficiency of workers. Employees stay more alert

and become less tired in air-conditioned offices and factories. They make fewer mistakes and have fewer accidents. Air conditioning also protects workers against high temperatures and harmful dust, smoke, and fumes. In stores and shops, air conditioning keeps merchandise clean. It also increases sales, because people like to shop in comfort.

Several industries, such as the electronics industry, work with delicate parts and therefore require air-conditioned *clean rooms,* which are free of dust or germs. Companies in these industries make or assemble equipment in such rooms because the tiniest speck of dust could prevent the equipment from working properly.

Large computers become warm when in use and are sensitive to dust. A computer may break down unless air conditioning removes this heat and keeps the surrounding air clean.

Metals and other materials expand as the temperature rises, and contract as the temperature drops. For this reason, air conditioning is used to control the temperature in factories that manufacture tools or parts for instruments, watches, cameras, and other precision products. Changes in temperature would change the size of such products.

Many nonmetallic materials, including textiles, paper, and tobacco, absorb moisture from the air. Too much moisture may make these materials stretch out of shape. Too little moisture in the air makes these materials dry and brittle.

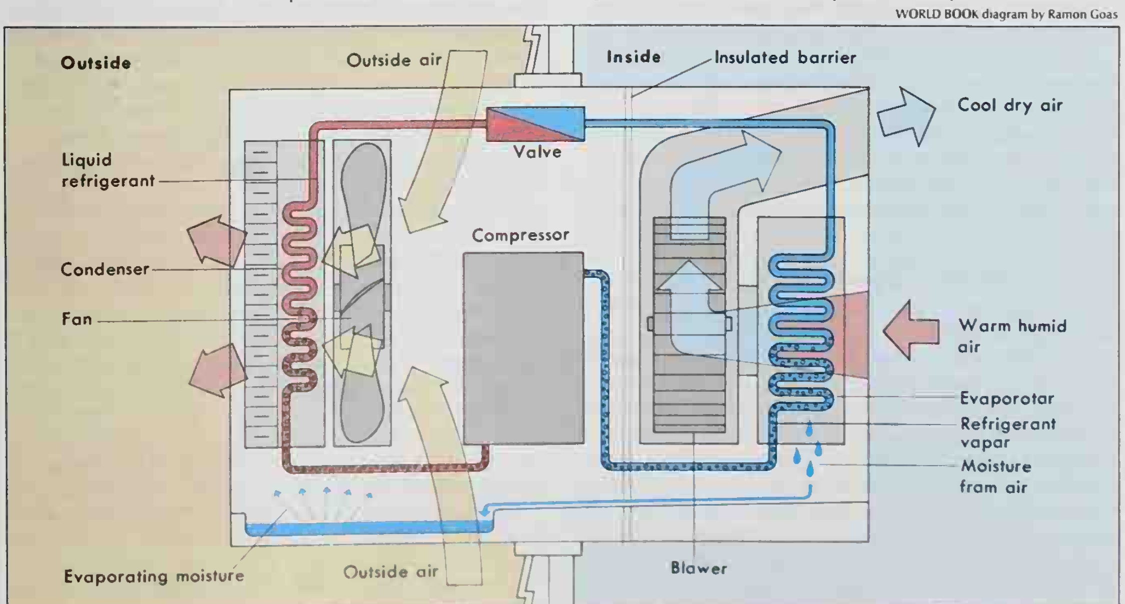
Almost all textile mills use air conditioning to control moisture so they can produce strong, uniform threads and fabrics. Some fibers, such as nylon and rayon, could not be made and woven into cloth without air conditioning. Even the sewing machines that mass-produce nylon stockings require proper temperature control. The needles of these machines are so small, and operate in such tiny spaces, that sudden temperature changes could cause them to jam and break.

Paper stretches in wet weather, and becomes brittle in dry weather. Air conditioning helps control moisture in printing plants so the paper will remain flexible and stay the same size. This makes possible high-speed printing of newspapers, magazines, and books throughout the year.

In bakeries, air conditioning controls the rising of bread dough. It also keeps flour from molding. Bread that is cooled in air-conditioned rooms has crack-free crusts.

In drug and chemical plants, air conditioning not only provides clean air but also removes germs from air. Air conditioning keeps moisture at the proper level so that powders, salts, and other chemical substances stay dry.

Air-conditioning systems in commercial buildings are being used increasingly for smoke control during fires. By controlling the airflow, the systems provide smoke-free areas for evacuation and fire-fighter access.

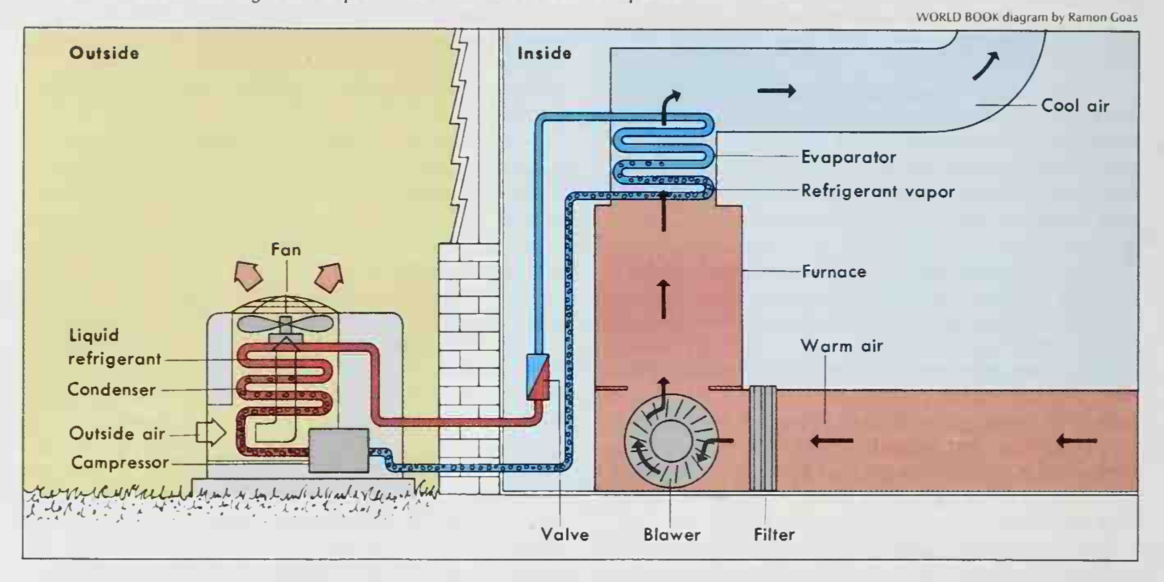


How air conditioners work

There are three main kinds of air-conditioning systems. *Summer air conditioning* cleans, cools, and removes moisture from air. *Winter air conditioning* cleans, heats, and adds moisture to air. *Year-round air conditioning* cleans and controls the temperature and moisture content of air throughout the year. All air-conditioning systems have some way of blowing, or circulating, the conditioned air through rooms.

Cleaning the air can be done in several ways. Some air conditioners force the air through *filters.* The filters usually consist of closely packed fiberglass wool or metal fibers that have been coated with a sticky oil or some other type of adhesive (see **Fiberglass**). As the air

How a window air conditioner works A window air conditioner cools room air by means of a refrigerant. The liquid refrigerant absorbs heat from the air and becomes a vapor as it flows through the evaporator. A compressor pumps the vapor to the condenser, which discharges the heat and turns the vapor back to liquid.



WORLD BOOK diagram by Ramon Goas

How home central air conditioning works

In a home central air conditioner, the refrigerant carries heat outside just as it does in a window unit. A system of *ducts* (pipes) and a blower on a furnace move the air cooled by the evaporator to all the rooms in the building. The compressor and condenser are in a separate unit outside.

WORLD BOOK diagram by Ramon Goas

passes through, the dirt, dust, and soot in the air stick to the fibers. Air can also be cleaned by blowing it through sprays of water called *air washers.* A central air conditioner that uses this method has a row of nozzles that squirt a fine mist of water into the air. The water rinses out the dirt. Central air conditioners may also be equipped with *electrostatic filters,* or *electrostatic precipitators.* These devices put a positive electric charge on the particles of dirt in the air. Negatively charged collector plates attract the positive particles out of the air (see **Air cleaner**). Some central air conditioners force the air through porous pieces of carbon, which absorb odors.

Drug firms and hospitals require extremely pure air. They usually have air conditioners equipped with special filters. These filters remove all dirt particles down to a size of $\frac{1}{85,000}$ inch (0.0003 millimeter). Air conditioners may also have special lamps that kill germs in the air with ultraviolet rays (see **Ultraviolet rays**).

Controlling the temperature. After an air conditioner cleans the air, it must cool it in summer and heat it in winter. Most people feel comfortable when the temperature of the air is between 68 °F (20 °C) and 75 °F (24 °C) in the winter and between 73 °F (23 °C) and 79 °F (26 °C) in the summer.

To cool the air, some air conditioners blow it through sprays of cold water. The same sprays that clean the air may also cool it. Most air conditioners blow the air over *coils* (large groups of tubes) that are filled with cold water or a chemical refrigerant. Refrigeration machines may be used to chill the water or refrigerant that flows through these coils (see **Refrigeration** [Mechanical refrigeration]). Other air conditioners may use cold water that comes from a well, a river, or a city's water system.

Most air conditioners used in large buildings heat air by blowing it over coils filled with hot water or steam. A boiler heated by a gas or oil burner produces the hot water or steam. In some air conditioners, electric heaters warm the air. These heaters have a screen of wires heated by electricity. The air is warmed as it passes through the screen.

Controlling the moisture. The evaporation of moisture from our skin helps cool our bodies. But in summer, air often becomes *humid* (moist). Humid air cannot pick up as much extra moisture as dry air can. We find it difficult to cool off in humid weather, because the air does not absorb the perspiration from our bodies. The amount of moisture that people lose as perspiration depends on their activities and emotions. For example, a crowd at a basketball game perspires more than an audience in a motion-picture theater. An air conditioner must remove warm, moist air from a room and supply cool, dry air. Otherwise, the air becomes sticky and we feel uncomfortable.

The amount of moisture in air compared with the amount it can hold is called the *relative humidity* (see **Humidity**). People usually feel most comfortable when the relative humidity is kept between 30 and 60 per cent.

Air conditioners can *dehumidify* (remove moisture from) air in several ways. Cold air cannot hold as much moisture as warm air can. When air conditioners cool air by passing it over cooling coils, the water or refrigerant in the coils can be made cold enough to cause the moisture in the air to *condense* (turn into a liquid). The same process occurs when the outside of a drinking glass becomes moist as it is filled with ice water.

Air conditioners also can remove moisture from air by passing it through sprays of cold water. These sprays cool the air enough to condense some of the moisture.

Moisture control is important in winter, too. Cold outside air contains little moisture. When this air is heated,

it becomes extremely dry. Such air dries the skin and may irritate the nose, throat, and lungs. To prevent these discomforts, air conditioners add moisture to the air in cold weather. They do this by passing air through sprays of water or over pans of heated water. The water evaporates into the air.

Circulating the air is important because most people feel uncomfortable in motionless air. The air in a room often becomes filled with moisture and odors. This air must be removed as conditioned air is blown in.

Fans blow conditioned air through the room. The air may be blown in directly or through *ducts* (pipes) that lead to various parts of a building. In large commercial buildings, other fans suck out used air. To eliminate smoke and odors, the fans *exhaust* some of the used air by blowing it out of the building. The remaining used air is returned to the air conditioner, where it is mixed with *ventilation air* drawn in from outside. This mixture of inside and outside air is then conditioned and returned to the cooled room. Eventually, an air conditioner replaces all the air in a room or building with ventilation air drawn in from outside. An air conditioner can circulate air through a room at a rate of about 15 to 40 cubic feet (0.4 to 1.1 cubic meters) per minute. The amount of air circulated through a room depends on the size and speed of the fan used in the air conditioner.

Kinds of air conditioners

Room air conditioners operate on electricity or gas, and are located partly in the room to be cooled. They are enclosed in a single cabinet. They blow the conditioned air directly into the room and do not have air ducts leading to and from them. The three chief types are (1) window air conditioners, (2) consoles, and (3) self-contained air conditioners.

Window air conditioners fit into the lower part of a window and can be moved from window to window. In the air-conditioning industry, these units are called *room air conditioners.*

Consoles are larger than window air conditioners and stand on the floor in the room. They must be near a window or a wall opening in order to obtain outside air.

Self-contained air conditioners are the largest room air conditioners. They may stand 7 feet (2 meters) tall, and can cool an entire large room, such as a restaurant.

Central air conditioners use electricity or gas. They can supply conditioned air to a number of rooms or to an entire building from one central source. Fans blow the conditioned air through air ducts from the air conditioner to the rooms.

Central conditioners have a number of advantages over other kinds. For example, all the equipment for air conditioning a large area is located in one place. This reduces the cost of cleaning and repairing. Central conditioners can also be *zoned.* That is, they can supply air of different temperatures to different parts of a building. A doctor with a crowded waiting room might want cooler air than a lawyer in a smaller office. Zoning makes it possible to serve both their needs.

Combination room and central air conditioners are used in large buildings. They combine the advantages of both types. One kind of combination system has a central conditioner to condition outside air. It circulates the conditioned air to a unit in each room. The room unit controls the temperature and moisture-content of the air.

Another type of combination system furnishes cold water or a refrigerant from a central refrigeration machine to a conditioner in every room. Each room conditioner has a fan, filter, and cooling coils to condition and circulate the air.

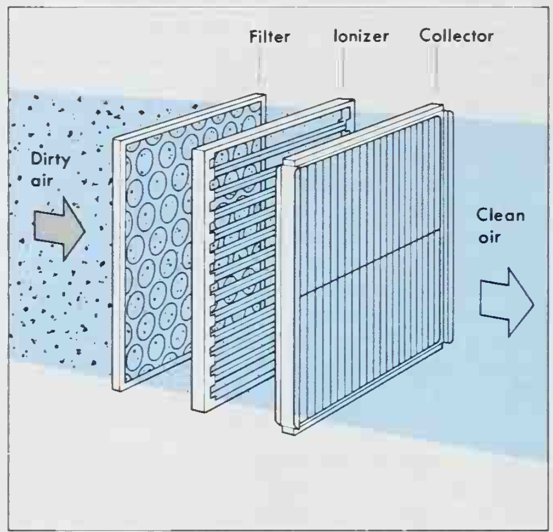
A third variety of combination system conditions a mixture of outside and inside air. This system supplies each room with cool, conditioned air through one duct, and warmed, conditioned air through another duct. A *mixing-box* unit in each room mixes the two air streams to provide the right temperature. Combination systems have the advantage of supplying conditioned air or a cooling fluid from a central source. This cuts the cost of maintaining them. At the same time, the individual room units allow the people in each room to adjust the temperature to suit their wishes.

Air conditioners for vehicles. In automobiles, the refrigeration unit is located under the hood near the engine. The engine drives the unit by means of a belt connected to the engine. Air ducts feed the conditioned air into the car.

Buses often have a separate motor to drive the refrigerating equipment. This equipment may be located either in the rear of the bus or under one side near the luggage compartment. The air conditioner is in the roof of the bus. It supplies cool, conditioned air to the seats through ducts running along the roof.

In a railroad passenger car, an electric motor or a gasoline engine drives a refrigeration unit located under the car. The air conditioner is mounted over the entrance at one end of the car. Fans in the conditioner blow the air through ducts to outlets that are located in the car.

Airplanes require special air-conditioning units. Much of the equipment is made of aluminum to save weight. The refrigeration and air-conditioning units for large airplanes are usually located in the wings. In smaller aircraft, these units may be in the body of the airplane. Air turbines drive the refrigeration equipment. Air ducts feed the conditioned air to different parts of the airplane.



On ships, the refrigeration equipment is installed in the engine room or in a mechanical equipment room. The air-conditioning units are located throughout the ship. Air-conditioning equipment for ships must be extra strong to withstand the rolling and pitching motion of the water. Special metals are used to resist corrosion by seawater.

Choosing a window air conditioner

Two facts should be kept in mind when selecting a window air conditioner. (1) The *capacity* (cooling power) of the air conditioner should be suitable for the room. (2) The electric power requirements for the air conditioner must match the electric system available for it.

Capacity of air conditioners. The size of a room and the number of people using it help determine the capacity of the air conditioner needed. So do the number, size, and direction of the windows in a room, the wattage of appliances and lights, and the amount of wall insulation.

An air conditioner that has a lower capacity than

WORLD BOOK diagram by Ramon Goas

An electrostatic filter, also called an *electrostatic precipitator,* removes particles of dust and smoke from the air. The ionizer gives the particles a positive electric charge. The negatively charged collector then attracts and holds the particles.

needed will not keep a room cool. An oversized unit will control the temperature, but it may not reduce excess humidity. Such a unit will run only a short time before the temperature falls. It may not even run long enough to remove much moisture from the air.

Manufacturers rate the capacity of air conditioners in four ways: (1) British thermal units, (2) watts and kilowatts, (3) tons of refrigeration, and (4) horsepower.

British thermal units. One British thermal unit (Btu) equals the amount of heat needed to raise the temperature of 1 pound (0.45 kilogram) of water from 59 °F to 60 °F (15 °C to 15.56 °C). The *Btu per hour* rating is the basic measurement for air conditioning, and should always be used to specify the capacity of an air conditioner. An air conditioner with a capacity of 12,000 Btu's per hour can remove enough heat from the air it is conditioning to raise 12,000 pounds (5,440 kilograms) of water one degree Fahrenheit each hour. The cooling capacities of room air conditioners range from 4,000 to 36,000 Btu's per hour.

Watts and kilowatts are the units used to measure air-conditioner capacity in the metric system. One watt equals 3.4 Btu's per hour.

Tons of refrigeration. One ton of refrigeration removes the amount of heat needed to melt 1 short ton (0.9 metric ton) of ice at 32 °F (0 °C) in 24 hours. A one-ton air-conditioning unit can remove 288,000 Btu's of heat in 24 hours, or 12,000 Btu's per hour (3,510 watts). A two-ton air-conditioning unit can remove twice this amount, and so on.

Horsepower measures the power needed to run the refrigeration equipment that cools the air. One horsepower equals 745.7 watts.

Electric power requirements. Local electrical codes govern the kind of motor that can be connected to different kinds of electrical systems. Most air conditioners that have a capacity rating of up to 14,000 Btu's per hour operate on 110-volt, single-phase current. Larger air conditioners need either 220-volt or 220-440-volt, three-phase current. See Electric generator (Kinds of AC generators).

Different air conditioners use various amounts of electricity to remove the same amount of heat. Engineers use a number, called the *Energy Efficiency Ratio* (EER), to measure how economically an air conditioner uses electricity. To find an air conditioner's EER, its Btu per hour rating is divided by the number of watts of electricity used by the unit. For example, an air conditioner that uses 600 watts to remove 5,000 Btu's per hour has an EER of 5,000 divided by 600, or 8.33. Most air conditioners have an EER of from 8 to 9. The higher the EER of a unit, the less electricity it uses—and the less it costs to operate.

History

The ancient Egyptians, Greeks, and Romans used wet mats to cool indoor air. They hung the mats over the doors to their tents and other dwellings. When wind blew through the mats, evaporation of the water cooled the air. The people of India later used this method to cool the royal palaces. About 1500, Leonardo da Vinci, the great Italian artist and scientist, built the first mechanical fan to provide ventilation. Water power turned the fan. In 1553, the English developed a rotary fan to ventilate mines.

Textile manufacturers made the first attempts at air conditioning. In 1719, a silk company in Derwent, England, installed a central system to heat and ventilate its mill. Early cloth makers in New England boiled water in huge pots near their looms to keep the air moist. Unfortunately, the heat injured the health of the workers and this method was discontinued.

About 1838, David B. Reid, an English scientist, provided the British House of Commons with a system to ventilate and humidify the air. In the mid-1800's, John Gorrie, an American, invented a cold-air machine to cool hospital rooms.

During the late 1800's, textile manufacturers in New England began using sprays of water to condition the air in their mills. In 1897, Joseph McCreery of Toledo, Ohio, received a patent for the type of spray now used in air conditioners.

By 1902, Alfred R. Wolff, a consulting engineer, had designed air-cooling systems for Carnegie Hall and several other buildings in New York City. That same year, Willis H. Carrier, a research engineer, designed the first scientific system to clean, circulate, and control the temperature and humidity of air.

In 1906, Stuart W. Cramer, a textile engineer from Charlotte, N.C., used the term *air conditioning* for the first time. Air conditioning became a recognized branch of engineering in 1911.

The Baltimore & Ohio Railroad installed the first air-conditioning system for trains in 1931. Air conditioning of apartments and homes also began during the 1930's. In 1939, Packard Motors introduced air-conditioning units for automobiles. The Greyhound Corporation installed the first bus air-conditioning systems in 1940. By the 1990's, about 70 percent of all of the housing in the United States had some form of air conditioning. In addition, most of the new single-family homes that were

built in the United States were equipped with central air conditioning.

Careers in air conditioning

Careers in air conditioning can be divided into five main fields: (1) designing, (2) manufacturing, (3) selling, (4) installing and servicing, and (5) teaching and research. College-educated engineers research and design air-conditioning systems. Skilled machinists, toolmakers, cabinetmakers, and similar craftworkers help manufacture air conditioners. Technical training, such as a degree in engineering, is often essential for positions in the selling and executive branches of air conditioning. Specially trained technicians, and operating and service engineers, install and maintain air conditioners.

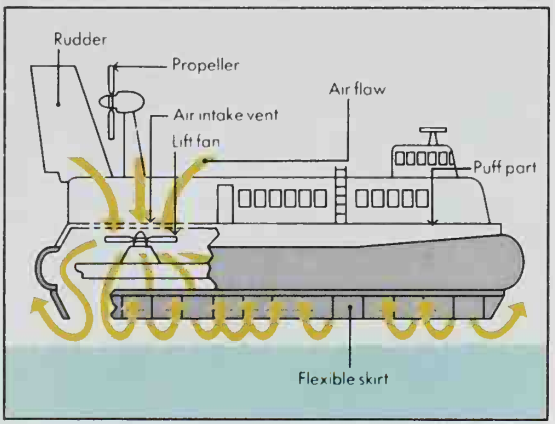
Air-cooled engine. See Gasoline engine (Cooling).

Air cushion vehicle (ACV) is a craft that travels on a layer of compressed air just above any kind of surface—land or water. The compressed air serves as an invisible cushion that eliminates almost all friction between the vehicle and the surface. ACV's, which are also known as *hovercraft,* can carry passengers, vehicles, and freight. Some ACV's can travel as fast as 80 miles (130 kilometers) per hour.

How an ACV works. An air cushion vehicle has one or more fans that suck air into the craft. The fans force the air underneath the vehicle, creating an air cushion between the ACV and the surface. ACV's are sometimes called *ground effect machines* because they use the surface to help trap the air.



A flexible rubberized skirt surrounds the lower edge of most ACV's. It fills with air forced in by the fans. The skirt enables the vehicle to travel over such rough obstacles as rocks and waves. Some ACV's have skirts only across the bow and stern. Rigid sidehulls run along the length of the craft. Such ACV's are called *surface effect ships* (SES's). They can be used only in water.

Gas turbines or lightweight diesel engines provide the power for the fans, and propellers drive the ACV forward. Most ACV's have small doors called *puff ports*

Textron Marine Systems

An air cushion vehicle can travel on land or on water. This vehicle is a U.S. Navy Landing Craft, Air Cushion (LCAC). It can cross rough shores to land troops and equipment.

WORLD BOOK diagram

A "cushion" of air under pressure supports an air cushion vehicle. A powerful fan creates the cushion by blowing air beneath the vehicle's flexible skirt. A propeller drives the craft forward. The pilot steers the vehicle with an airplane-type rudder.

and either rudders or propellers for steering. These three devices enable the vehicle to travel backward, forward, or sideways, or to hover or turn.

History. ACV principles were recognized as early as the mid-1800's, but the technology did not exist for building a practical model. In the early 1900's, a limited number were built. The Austrian Navy demonstrated one in 1916. In the mid-1950's, Christopher Cockerell, an English inventor, improved the basic design. In the early 1960's, Britain, Japan, the Soviet Union, the United States, and other countries all tested ACV's.

In the late 1960's, the U.S. Navy and Army began to use ACV's in the Vietnam War for patrol duty and rescue missions. In 1968, the British began to use ACV's to carry passengers and cars across the English Channel. Development of *hoverbarges*—that is, ACV's that are pulled or pushed by another vehicle—began in the 1960's. In 1972, Canadian researchers discovered that ACV's could be used to break ice on waterways.

Today, manufacturers produce a number of models that vary in size, speed, and power. Modern ACV's accomplish many tasks. However, most ACV's are used for military missions. Russia and the United States are the world's largest users of the craft.

In the late 1950's, Jean Bertin, a French engineer, invented a special train called a *tracked air cushion vehicle* (TACV) or *air train.* This train runs only on land, and it requires tracks. It does not actually touch the tracks but uses them as a guide. The train has a *linear electric motor,* which includes electromagnets in the underside of the vehicle (see **Linear electric motor**). The tracked air cushion vehicle is powered by magnetic forces between the track and the electromagnets. It may also be powered by a jet engine.

A vehicle called a *magnetic levitation train,* or *maglev train,* resembles the TACV. But a maglev train relies on a magnetic force between the vehicle and the guide rail—rather than on a cushion of compressed air—to hold the vehicle above the track. John D. Bogus

Air force

Air force is the branch of a nation's armed forces responsible for military operations in the air. An air force consists of pilots and other personnel, aircraft, support equipment, and military bases. Some air forces also have guided missiles and spacecraft.

Most countries have some type of air force. More powerful nations have an independent air force equal in rank to the other branches of the nation's armed forces. These countries usually also have an air force unit in their army and navy. Many smaller, less powerful nations have an air unit as part of their army or navy.

Air forces differ greatly in size and fighting strength, depending on a nation's wealth, technology, and national defense needs. The large air forces of industrialized nations have modern bombers, fighters, transport planes, helicopters, and other aircraft. Most developing nations cannot afford the advanced technology required to build a modern air force. But some have assembled relatively strong air forces through loans and trade with industrialized nations. Many smaller developing nations have air forces that consist of older aircraft.

The United States and Russia have the most powerful and complex air forces. These forces include thousands of aircraft and long-range missiles, some with nuclear warheads. Other powerful nations, including China, France, and the United Kingdom, also have such missiles.

Until the development of airplanes and guided missiles in the 1900's, nations relied on armies and navies for military power. The operations of these forces, however, are limited by land and sea barriers. Today, armies and navies remain extremely important. But the main striking force of the most powerful nations consists of airplanes and guided missiles.

Timothy M. Laur, the contributor of this article, is a consultant and lecturer on military issues. He is a retired lieutenant colonel in the United States Air Force and author of An Encyclopedia of Modern Military Weapons.

The role of air forces

A nation's air force may have several different roles depending on the country's security needs. Air forces within an army or navy support the operations of that branch. A navy's air force, for example, may operate attack and *reconnaissance* (observation) planes from aircraft carriers to obtain information about operations in enemy territory. A navy's air force may also patrol its country's coastline. An air force that serves as a separate military branch, however, usually has several roles related to establishing control of the air. These roles include (1) combat, (2) defense, and (3) transport.

Combat missions involve fighting directly against an enemy force. The two chief types of combat missions are *strategic* and *tactical*. In strategic missions, air forces operate over long distances, usually traveling from one continent to another. The most common strategic missions involve attacks with bombs and long-range missiles against specific targets in enemy cities and indus-

trial areas. Strategic attacks are designed to destroy the enemy's ability and desire to fight.

Tactical missions are short- or medium-range operations carried out in cooperation with ground or sea forces in battle. Such missions include attacks on enemy ground forces and *counter air tactical missions.* In these missions, fighter planes may attack enemy aircraft to gain control of the air over a battle area. In *interdiction attacks,* aircraft strike transportation networks and other targets behind enemy lines. Such attacks prevent enemy forces and supplies from reaching the battlefield.

Defense missions protect a nation's territory from enemy attack. Advanced air forces use radar stations and satellites to detect surprise attacks by enemy bombers or missiles. In case of such an attack, an air force uses missiles and fighter planes to shoot down enemy bombers and missiles.

The threat of a counterattack can also serve as part of a nation's air defenses, especially among nations that have nuclear weapons. Nations may avoid launching a nuclear attack because of their fear of a counterattack.

Transport missions, also called *airlifts,* support a nation's combat operations by moving troops and equipment quickly by air. In a strategic airlift, aircraft transport troops and equipment over long distances. A tactical airlift provides air support to battlefield operations. For example, aircraft may drop paratroopers and supplies in a battle area or behind enemy lines. In peacetime, air forces may transport food and other supplies to areas struck by disaster.

Other missions include reconnaissance and air rescue. Reconnaissance missions gather military information using visual observation, or cameras, radar, and other sensing devices aboard aircraft and satellites. Air rescue missions use small airplanes or helicopters to rescue people trapped in dangerous areas.

The organization of air forces

The leader of an independent air force may be a chief of staff or air marshal and hold the rank of general. In the U.S. Air Force, however, the highest authority is the secretary of the Air Force, a civilian appointed by the President. Air forces of smaller countries often come under the command of the army or navy.

The *squadron* is the basic administrative unit of air forces. A squadron usually consists of aircraft of one type or model. Most fighter and attack squadrons have 18 to 24 assigned aircraft, which are usually grouped into smaller units of 2 to 4 planes called *flights.* Bomber squadrons typically have from 10 to 19 assigned aircraft. Two or more squadrons form units called *groups* or *wings.* In large air forces, these units may combine to form larger *divisions* or *commands.*

Aircraft and missiles

Aircraft are usually classified by their function. The main types of aircraft are (1) attack and fighter aircraft, (2) bombers, (3) transport aircraft, and (4) reconnaissance aircraft.

Attack and fighter aircraft are designed for speed and maneuverability in combat. They usually have a crew of one or two and carry missiles or bombs, depending on their mission. These aircraft attack enemy planes and ground targets or defend against air attacks.

Shaun Harris, Photo Press

Paratroopers drop from planes into battle areas or behind enemy lines, often surprising the enemy. *Above,* paratroopers from Britain's Royal Air Force train for an assault by air.

Bombers are usually large, medium-range or long-range planes that carry a combination of bombs and guided missiles for striking strategic targets. Only a few nations with powerful air forces have bombers. Bomber crews range in size from about four to six people.

Transport aircraft carry troops or cargo. The crew of a typical transport plane includes a pilot, copilot, navigator, flight engineer, and one or more *loadmasters* responsible for the cargo or passengers.

Reconnaissance aircraft carry cameras or electronic sensors to gather information about enemy forces. Reconnaissance aircraft include both airplanes specifically designed for reconnaissance and modified versions of other aircraft.

Other aircraft include trainers, tankers, and helicopters. Trainers are used to train pilots. Tankers refuel other aircraft in flight. Helicopters serve a variety of functions. Some, called *gunships,* carry guns and missiles and are used in combat. Others transport troops and equipment over short distances.

Missiles used by air forces may be launched from the ground or from aircraft. Ground-launched strategic missiles include intercontinental ballistic missiles (ICBM's) and intermediate-range ballistic missiles (IRBM's). ICBM's can deliver a nuclear warhead to a target up to 9,200 miles (15,000 kilometers) away. IRBM's can reach

Sovfoto

Russian-made MIG aircraft, such as this MIG-29K fighter from the Russian Air Force, are common in the world's air forces. India, Iraq, Poland, and many other countries fly MIG's.

from about 1,700 to 3,400 miles (2,700 to 5,500 kilometers). In some nations, such as in the United States, the air force is responsible for ICBM's. But in others, including China and Russia, these missiles fall under a separate command. Air forces defend against ballistic missile attacks with ground-launched antiballistic missiles (ABM's).

Air-launched missiles include both strategic and tactical missiles. Bombers carry air-launched strategic missiles, such as the cruise missile, that can hit targets hundreds of miles or kilometers away. Fighter and attack aircraft and helicopters fire tactical air-to-air missiles (AAM's) at enemy aircraft and air-to-surface missiles (ASM's) at ground targets.

Major air forces of the world

The power of an air force depends on the quality of its technology, training, and equipment. The world's most powerful air forces have advanced aircraft, well-trained crews, and efficient maintenance and supply systems. They include the air forces of the United States, Russia, China, Ukraine, France, India, the United Kingdom, Germany, and Israel. Other important air forces include those of Italy, North Korea, and Turkey. However, these forces are smaller and less technologically advanced.

The United States Air Force has about 2,500 active fighter and attack aircraft and about 200 bombers. The Air Force also operates several satellite and radar systems. It has about 350,000 members, along with more than 70,000 in the Air Force Reserve. An additional 110,000 people serve in Air National Guard units, which are administered by the states. The U.S. Air Force commands about 700 ICBM's but no IRBM's. Under a 1987 treaty, the United States and the Soviet Union agreed to eliminate their IRBM's.

The U.S. Army, Navy, Marine Corps, and Coast Guard all have their own air force units. The U.S. Navy has the world's largest air arm with more than 1,400 combat airplanes and more than 500 armed helicopters. The U.S. Army air unit includes about 1,500 armed helicopters.

The Russian Air Force has about 2,700 active combat aircraft, including about 2,300 fighters. The Air Force has more than 180,000 members. A separate strategic force controls about 700 ICBM's in Russia and about 70 in Ukraine. Another force for space operations launches and operates military satellites. The Russian Navy's aviation branch has about 250 combat airplanes and about 100 armed helicopters.

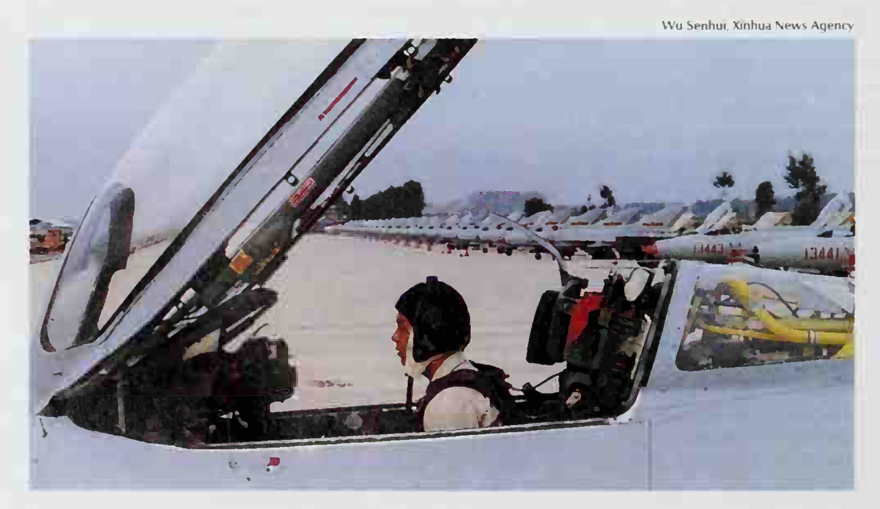
The Chinese Air Force has more than 3,000 fighter and attack planes and about 350 bombers. Many of its planes are based on Russian designs. About 420,000 people serve in the Air Force. China's Navy operates about 550 additional combat aircraft. China also has about 20 ICBM's and 100 IRBM's under a separate strategic force.

The Ukrainian Air Force has about 900 combat aircraft and 25 bombers. It has about 95,000 members.

The French Air Force has about 500 combat aircraft, mostly fighter and attack planes. The force has about 60,000 members. A separate strategic air force operates about 60 bombers equipped with IRBM's. The French Navy has about 50 combat airplanes and 30 armed helicopters.

The Indian Air Force has about 800 combat aircraft, including about 350 fighters and more than 30 attack helicopters. India's Air Force also controls a large arsenal of surface-to-air missiles. About 150,000 people serve in the Air Force. India's naval air force has about 40 additional combat airplanes and about 70 armed helicopters.

The British air force, called the Royal Air Force (RAF), has more than 400 active combat aircraft, mostly fighter and attack airplanes. It has about 55,000 members. The Royal Navy's air arm has about 30 additional combat airplanes and more than 100 armed helicopters.



The German Air Force, called the Luftwaffe, includes about 450 active attack and fighter aircraft, with about 50 additional combat airplanes and 50 armed helicopters in the navy's air unit. About 73,000 people serve in the Luftwaffe.

The Israeli air force has about 450 active fighter and attack aircraft and about 36,000 members. It is one of the largest and most capable air forces in the Middle East, with highly experienced pilots.

History

Early air forces. The first air force was established by France in 1794, during a war against several other Eu-

Wu Senhui, Xinhua News Agency

Skilled pilots are essential to an effective air force. Like all military pilots, this pilot from the Chinese Air Force must spend many hours training before he can fly sophisticated aircraft into dangerous combat areas.

Bettmann

The first air force was a French balloon corps, formed in 1794. Before airplanes were invented in 1903, warring nations used balloons to observe enemy troops and to drop bombs.

ropean nations. The air force flew large balloons filled with hot air or gas. The French used the balloons to observe movements of enemy troops.

The first air attack took place in 1849. Austria controlled much of Italy at that time, and the people of Venice revolted. The Austrians sent unmanned balloons carrying time bombs over the city. Some of the bombs exploded as planned. But the wind changed direction and blew several balloons back over the Austrian troops, where the rest of the bombs exploded.

During the American Civil War (1861-1865), both the Union and Confederate armies used balloons. The Union Army organized a balloon corps to direct artillery fire and observe Confederate troop movements. Almost every major army in the world soon established a balloon corps.

Balloons became much less important in warfare after Orville and Wilbur Wright made the world's first airplane flight in 1903. By 1909, France, Germany, Britain, Russia, and the United States had purchased planes for their armed forces. In 1912, Britain established the Royal Flying Corps as the air arm of the Royal Army and Navy. In 1918, the corps became the Royal Air Force, the first independent air force.

World War I began in 1914. In the war, the Allies, who included Britain, France, Russia, and the United States, fought the Central Powers, who included Germany and Austria-Hungary. At that time, most airplanes flew at a maximum speed of about 75 miles (120 kilometers) per hour. They could reach an altitude of about 10,000 feet (3,000 meters). By 1918, when the war ended, the maximum speed of aircraft had reached about 120 miles (190 kilometers) per hour, and maximum altitude had more than doubled. Planes also had become much more maneuverable.

At the beginning of the war, the fighting nations used planes only for observing enemy ground movements. Aircraft soon began to exchange gunfire, but many could not shoot forward because the plane's propeller was in front. Bullets might shatter the spinning blades of the propeller. In 1915, a Dutch designer, Anthony Fokker, developed a machine gun for the Germans that fired only when the propeller blades were not blocking the muzzle. The Allies began to use a similar gun in 1917.

During the war, pilots fought air battles called *dogfights,* and fliers who shot down five or more enemy planes became known as *aces.* Toward the end of the war, battles between squadrons of airplanes replaced most combat between single pilots. Early in the war, pilots had dropped bombs by hand. Later, they used mechanical devices to release the bombs. By 1917, some planes could carry up to 3,000 pounds (1,400 kilograms) of bombs.

In September 1918, American officer Billy Mitchell directed the largest air assault of the war. He commanded about 1,500 Allied aircraft in a mission over St.-Mihiel in France, where the Germans had advanced. The Allied planes gained control of the air, dropped bombs behind the German lines, and attacked enemy ground forces. Two months later, the Allies won the war.

The growth of national air forces. Although many nations reduced their armed forces after World War I, the success of the airplane caused them to gradually develop their airpower. This policy often produced competition between a country's new air service and older army and navy. In the United States, for example, Billy Mitchell and other aviation leaders argued vigorously for greater emphasis on airpower. Mitchell became so bitter in his criticism of the U.S. defense program that he was court-martialed for defying his superior officers. In 1946, after events had confirmed many of Mitchell's predictions, he was awarded the Medal of Honor, the nation's highest military decoration. During the 1920's and early 1930's, France, Germany, Italy, and Sweden formed independent air forces.

World War II. Airpower played a vital role in deciding the outcome of World War II. In the war, Germany, Italy, Japan, and other Axis powers fought the Allies, who included Britain, Canada, China, the Soviet Union, and the United States.

The war began in 1939 when Germany invaded Poland. The Germans used a new method of warfare called *blitzkrieg* (lightning war). Germany's air force, the Luftwaffe, bombed Polish troops, destroyed airfields, and struck at key cities, highways, and railroads. On the ground, tanks and infantry overwhelmed the Polish forces. Between April and June 1940, Germany attacked and defeated Denmark, Norway, Luxembourg, the Netherlands, Belgium, and France.

The Germans planned to invade Britain next, but first they had to defeat the Royal Air Force. In July 1940, the

Luftwaffe started to bomb British ships and ports. German air raids on London began in September. The RAF was outnumbered, but it had better planes and pilots than the Luftwaffe. The British also had developed radar and a decoding device that enabled them to read coded German messages. Both developments were carefully guarded secrets that helped the RAF intercept Luftwaffe raids. By October, the RAF had shot down more than 1,700 attacking planes and had lost about 900 of its own. Germany postponed its plans to invade the United Kingdom, but air raids on British cities continued.

The United States entered the war on Dec. 8, 1941, the day after about 360 Japanese aircraft attacked the U.S. fleet at Pearl Harbor in Hawaii. The attack destroyed or damaged 21 ships and more than 300 planes, temporarily crippling the Pacific Fleet and Hawaii's air defense.

In mid-1942, American airpower halted Japanese advances in the Pacific in two important battles at sea. In the Battle of the Coral Sea, in May, planes based on aircraft carriers did all the fighting. The opposing warships did not fire a shot at one another. Japan lost more planes, but fewer ships, than the United States lost in the battle. Neither side won, but the battle prevented a Japanese assault on New Guinea. A month later, in the Battle of Midway, Japan lost 4 aircraft carriers and more than 200 planes. The United States lost 1 carrier and about 150 airplanes. The battle blunted Japan's naval strength for the rest of the war and ended the threat of a Japanese attack on Hawaii and the United States.

By mid-1942, Japan had captured large parts of China and had cut off the country's main supply routes. To help China continue fighting Japan, Allied forces flew supplies from India to China over the Himalaya, the world's tallest mountain range. This dangerous route was called the "Hump." During this airlift, which lasted almost three years, the Allies carried about 650,000 tons (590,000 metric tons) of supplies to China.

The Allies attacked Germany in 1943, when the United Kingdom and the United States started a bombing offensive that lasted almost until the end of the war. The RAF bombed German cities at night, and American planes attacked enemy industries during the day. In 1944, the Luftwaffe began to use jet fighter planes. These planes could fly nearly 550 miles (885 kilometers) per hour, compared with about 400 miles (640 kilometers) per hour for propeller-driven fighters. Germany also developed the first guided missiles, the V-1 and V-2. In 1944 and 1945, the Germans fired more than 12,000 missiles at enemy cities. But these technological advances came too late to affect the outcome of the war. Germany surrendered in May 1945.

In August 1945, American B-29 bombers dropped atomic bombs on the Japanese cities of Hiroshima and Nagasaki. The bombers had flown from Tinian Island, 1,360 miles (2,189 kilometers) away. Japan surrendered in September, and the war ended.

The development of jet aircraft in the late 1930's and early 1940's greatly increased the range and speed of attacking planes. In 1939, a German Heinkel He 178 made the first successful jet-powered flight. By 1944, Germany had developed the Messerschmitt Me 262, the first jet to fly combat missions. The first American jet plane, the Bell XP-59, flew in 1942 but was little used in World War II. After the war, several nations, including the United Kingdom, the Soviet Union, and the United States, rapidly developed jet-powered air forces. Soon each of these nations operated a fleet of jet fighters and long-range bombers. By the late 1950's, France and China also began developing jet-powered air forces.

Air forces in the nuclear age. The United States emerged as the most powerful nation at the end of World War II. It was the only nation with atomic weapons and the aircraft to use them. But the Soviet Union soon began to challenge the United States, competing for power and international influence in a struggle known as the *Cold War*. In 1949, the Soviet Union tested its first atomic bomb. Several other nations have developed nuclear weapons since then.

The Soviet Union successfully tested its first ICBM in 1957, several months before the first successful United States test. The Soviets also launched the first space satellite in 1957. The United States and the Soviet Union competed for supremacy in missiles and space. They also developed *antiballistic missiles* (ABM's) designed to destroy enemy missiles in flight. To provide warning of a missile attack, the two nations set up missile detection systems on the ground and in space.

By the late 1960's, the number of missiles and nuclear warheads had grown alarmingly large. In 1969, the United States and the Soviet Union began a series of conferences in an effort to limit each country's missile strength. After several more conferences in the 1970's and 1980's, they agreed to eliminate their IRBM's. See **Arms control.**

Many smaller nations established strong air forces during the 1980's by obtaining aircraft from the United States or the Soviet Union. These nations included Finland, Hungary, Kuwait, and Saudi Arabia.

The Soviet Union began withdrawing its forces from Eastern Europe in 1990. In 1991, the United States and the Soviet Union agreed to reduce their long-range missiles and bombers, including their ICBM forces, by about a third. They also ended a continuous alert for long-range bombers carrying nuclear weapons and took other steps to reduce the threat of a nuclear air attack. This alert had been in effect in the United States since 1957. In late 1991, the Soviet Union broke up. These developments reduced the threat of nuclear war and the need for huge armed forces. As a result, most major air forces made cuts in personnel and equipment during the 1990's.

Air forces in limited wars. Fear of a massive nuclear war has helped prevent nations with nuclear weapons from using them. In all wars fought since World War II, nations restricted the weapons they used, the targets they attacked, and the areas of battle in order to avoid a nuclear conflict. In such wars, called *limited wars,* air forces played an important role.

The Korean War (1950-1953) brought the first combat between jet aircraft. The United States and other members of the United Nations aided South Korea, and the Soviet Union and China assisted North Korea. United States military leaders limited attacks on military targets, but airplanes often fought each other. As many as 150 jet fighters took part in some air battles. Each side adopted the principle of *asylum,* which allowed aircraft to withdraw from the battle zone without being pursued. Neither side won complete victory in this war.

During the Vietnam War (1957-1975), the United States supported South Vietnam, and the Soviet Union and China backed North Vietnam and the Viet Cong rebels of South Vietnam. From 1965 to 1968, the U.S. Air Force and the air arm of the U.S. Navy conducted frequent bombing raids against North Vietnam and later attacked targets in South Vietnam, Cambodia, and Laos. The U.S. Air Force used helicopter gunships to locate and attack enemy forces in the jungles and mountains. United States helicopters also rescued downed aviators, transported the wounded, and carried supplies and troops. In 1969, the United States began withdrawing its troops from Vietnam. The United States removed the last of its troops and stopped its air attacks in 1973. Two years later, the war ended with a North Vietnamese and Viet Cong victory.

Wars in the Middle East. In 1967, the Israeli Air Force destroyed most of the air forces of Egypt, Jordan, and Syria in the Six-Day War. Egypt rebuilt its air force and, in 1973, staged a surprise attack with Syria against Israel. For a brief period, Egypt established control of the skies. Israel's airpower, however, regained control and helped drive back the attackers. An airlift of supplies from the United States also helped Israel win the war.

In the Persian Gulf War in 1991, airpower played a decisive role. In that war, a coalition of nations led by the United States drove Iraq out of Kuwait. Before the war began, the coalition moved huge amounts of equipment to the Persian Gulf region in one of the largest airlifts in history.

Coalition air forces began the war in mid-January 1991 with massive bombing of targets in Iraq and Kuwait. The United States Air Force used precision-guided "smart" bombs and the F-117 "stealth" fighter-bomber. The special design and surface materials of "stealth" bombers make them difficult to detect with radar. The coalition quickly gained control of the air, destroying many Iraqi aircraft on the ground and forcing many others to flee to Iran. When the coalition launched a ground attack in late February, the air war had so devastated the Iraqis that they surrendered within days. Timothy M. Laur

Air Force, Department of the, is one of the three military departments within the Department of Defense of the United States government. It is located in Washington, D.C., and operates as Air Force headquarters. The department provides support for national and international policy by organizing, training, and equipping the Air Force. Its major divisions include the secretariat and the air staff.

The *secretary of the Air Force,* a civilian, heads the department under the direction of the secretary of defense, and ranks equally with the secretaries of the Army and Navy. The principal civilian aides to the secretary of the Air Force include an undersecretary and three assistant secretaries.

The *chief of staff of the Air Force,* a general, is the secretary's chief military adviser. The chief of staff heads the air staff; supervises such members and units of the Air Force as are determined by the secretary; and is a member of the Joint Chiefs of Staff, a military group that advises the U.S. president. A vice chief of staff assists the chief of staff.

Congress set up the department as an executive agency within the National Military Establishment in 1947. Before then, the Department of War controlled military aviation. In 1949, the Department of the Air Force became a military agency.

U.S. Air Force demonstration pilots, called Thunderbirds, fly their F-16 jets in close formation. The Thunderbirds perform at air shows in the United States and other countries.

United States Air Force

Air Force, United States, is the branch of the U.S. armed forces responsible for most military operations in the air and in space. Air Force *reconnaissance* (information-gathering) satellites and aircraft constantly scan the earth for signs of hostile activity. The Air Force is ready to attack immediately with conventional or nuclear weapons. The Air Force also supports ground troops in battle and protects them from air attack. Air Force transport planes deliver troops and supplies.

Because the Air Force needs to use advanced technology, it has a large research and development organization, with laboratories and testing centers throughout the United States. In addition, thousands of civilian scientists and engineers at universities and in corporations conduct research for the Air Force. The Air Force has cooperated with the National Aeronautics and Space Administration (NASA) to send astronauts and satellites into space. The Air Force also tracks hurricanes, forecasts weather, and carries help to disaster victims.

The Air Force has about 350,000 men and women on active duty throughout the world. In addition, about 190,000 people serve in the Air Force Reserve or the Air National Guard. The Air Force also employs about 140,000 civilians. The Air Force has about 3,600 active aircraft and about 600 *intercontinental ballistic missiles* (ICBM's), long-range missiles that can reach targets up to 9,200 miles (15,000 kilometers) away.

Wayne Thompson, the contributor of this article, is a historian at Headquarters United States Air Force.

The Air Force's official colors are ultramarine blue and Air Force yellow. Its official song is the "United States Air Force Song," which begins, "Off we go into the wild blue yonder."

The Air Force is the youngest branch of the United States armed forces. Congress created the Air Force in 1947 by reorganizing the Army Air Forces as a separate branch. The Army Air Forces developed from an Aeronautical Division that the Army Signal Corps set up in 1907.

Life in the Air Force

Men and women who serve in the United States Air Force give up some of the freedoms they protect for their country. They must go wherever they are sent, even on missions that may put their lives in great danger. The United States Air Force has about 90 major bases, many of which are overseas. Most Air Force members serve abroad at some time.

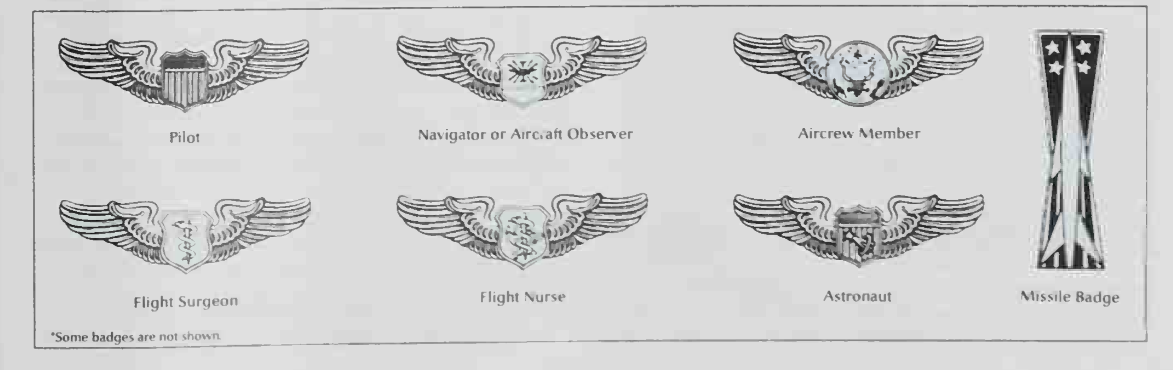
Recruit training. After enlisting in the Air Force, recruits receive six weeks of basic military training at Lack-

Grade insignias for officers

Air Force officers wear insignias made of metal or of thread or wire embroidery. Insignias decorate caps, shirt collars, or shoulders. Shoulder-board insignias are shown here.

U.S. Air Force

Dress uniforms for Air Force enlisted personnel are shown here. The uniforms for Air Force officers are similar, but officers' uniforms have grade insignias on the shoulder.



Grade insignias for enlisted men and women

The insignias of enlisted personnel, shown here, are worn on the sleeves of the uniform. Similar insignias are worn on the collar or shoulder of certain uniforms.

Badges*

Air Force badges, displayed here, show the qualifications and area of specialization of personnel. Aircraft crews wear wing badges. Missile crews wear missile badges.

land Air Force Base near San Antonio. Through marching, exercise, and classroom studies, recruits learn about teamwork in a military environment. Graduates of basic training learn a job specialty. They may reenlist after their minimum four or six years of service. See **Lackland Air Force Base.**

Officer training. The Air Force offers several programs for training officers. The programs include those of the Air Force Academy near Colorado Springs, Colorado; Air Force Reserve Officers Training Corps (AFROTC) in colleges and universities; and the Officer Training School (OTS) at Lackland Air Force Base.

Air Force women are trained, administered, and paid under the same policies as are Air Force men. Before the establishment of the Air Force in 1947, many members of the Women's Army Corps (WAC) were assigned to the Army Air Forces.

During World War II (1939-1945), more than 40,000 "Air Wacs" served at air bases in the United States and in other parts of the world. More than 1,000 civilians served as Women Airforce Service Pilots, also known as WASP's, under the leadership of aviation pioneer Jacqueline Cochran (see **Cochran, Jacqueline**). The WASP's flew aircraft from factories to air bases in the United States.

In 1948, women became a permanent part of the armed forces. Women in the Air Force became known as WAF's. The Air Force dropped this term in the 1970's. The term *airman* is now used for all Air Force enlisted military personnel. About 17 percent of Air Force military personnel are women.

Careers in the Air Force provide opportunities for advanced education and promotion. Enlistment may prepare a person for a civilian job or an Air Force career. The Air Force offers jobs in more than 40 career fields. Applicants must be at least 17 years of age and not older than 34. They also must pass the Air Force's physical and written examinations. Air Force military personnel may retire after 20 years of service. But many personnel stay on active duty for 30 years and some even longer.

Members of the Air Force receive a base pay that is determined by their rank and length of service. They may receive extra money for special tasks, such as flying a plane or taking part in combat. The Air Force also pays for *quarters* (housing) or *subsistence* (food) when airmen are unable to live or eat on base. All Air Force personnel on active duty are eligible for 30 days' *leave* (vacation) a year. The Air Force provides free medical care to airmen and their families.

The purpose of the Air Force

Since World War I (1914-1918), the most powerful countries have built large air forces. Air forces are the best defense against enemy airpower, and they can do great harm to enemy ground and sea forces. Air forces can attack targets anywhere in the opening minutes of a war.

Defense and deterrence. The people of every nation understand the terrible destructive power of nuclear and conventional weapons. As long as a potential enemy is unwilling to risk an exchange of attacks, the Air Force serves its primary purpose—to deter war. However, the Air Force must remain on alert for an enemy missile or bomber attack and must be prepared to respond to such an attack.

The U.S. Air Force has developed an extensive warning system to give the United States time to launch its offensive air weapons before they could be destroyed by a missile or bomber attack. The U.S. early warning system is managed by the North American Aerospace Defense Command (NORAD), which maintains a command center under Cheyenne Mountain near Colorado Springs. The most important parts of the system are reconnaissance satellites that orbit over various parts of the world.

On the ground, the Ballistic Missile Early Warning System (BMEWS) radars in Alaska, Greenland, and the United Kingdom have been upgraded and supplemented by radars in Massachusetts, Georgia, Texas, and California. Enemy bombers or *cruise missiles* flying over Alaska or Canada might be detected first by the North Warning System line of radars. Cruise missiles are jet-powered missiles that fly at low altitudes to avoid radar detection. A radar system in Maine can detect aircraft and cruise missiles approaching the east coast of the United States. See **North Warning System.**

The Air Force also carries radar aboard its Airborne Warning and Control System (AWACS) planes. In addition to performing its early warning function, an AWACS plane can fly to another part of the world and control U.S. air strikes. AWACS planes flew such missions in 1991, during the Persian Gulf War.

Offense. The most important use of the Air Force during war is to attack the enemy. Air attack can hit unexpectedly, at long range, and with devastating power. Each flight a combat plane makes against the enemy is called a *sortie*. An attack by one or more planes is a *combat mission*. If 10 planes fly in a group, the group flies 1 combat mission, but 10 sorties.

Tactical air attacks are the direct help given to ground or sea units in battle. Tactical air units fight to control the air over a battle area by destroying planes in the air and on the ground. They attack enemy troops and supplies to *interdict* them—that is, keep them from reaching the battlefront. They provide *close support* for ground troops, attacking specific targets for them.

Strategic air attacks hit far behind the battle lines. Such attacks destroy the enemy's industries and war materials. They also ruin the enemy's transportation network so troops and supplies cannot be moved into battle. Strategic air attacks are designed to destroy the enemy's capability to make war or its will to fight.

Peacetime emergencies. Prompt action by the Air Force may at times relieve emergencies that are short of war. The Berlin Airlift was a good example of such action. In 1948, the Soviet Union tried to force the Allies out of West Berlin with a ground blockade. The plan was defeated when the U.S. Air Force, the French Air Force, and the Royal Air Force of the United Kingdom created an effective aerial supply line to the city. The U.S. Air Force also charts the courses of hurricanes and gives advance warning to people living in the path of such storms. In times of disaster, the Air Force has flown emergency medical supplies into the affected areas.

Planes and weapons of the Air Force

The United States Air Force has many kinds of aircraft.

A few are driven by propellers, but jet engines drive most Air Force planes today. Many planes carry only a pilot. Others have a crew of several members that may include a copilot, navigator, and flight engineer. Some aircraft are guided only by electronic devices.

Planes of the Air Force are designated by both letters and numbers. A letter in front of the numbers refers to the basic mission of the plane, and the numbers designate the model. Basic missions include *A,* attack; *B,* bomber; *C,* cargo transport; *F,* fighter; *H,* helicopter; *K,* tanker; *R,* reconnaissance; and *T,* trainer. For example, an F-15 is a fighter aircraft.

A letter following the numbers indicates a general modification of the design. The original design is designated *A,* but often this letter is not used. The first modification is designated *B;* the second, *C;* and so on. Thus, the fourth modification (the fifth general design) of the F-15 is the F-15E. Some designations have an additional letter indicating a special modification. This letter appears in front of what would otherwise be the first letter. For example, an AC-130 is a C-130 to which guns have been added to convert it to an attack aircraft.

Bombers drop explosives on enemy targets. They are equipped with radar and bombsights to find the target and direct bombs to it. The navigator guides the pilot over the target, then releases the bomb. Bombers also launch missiles. The B-52 is the oldest American bomber in service. Its maximum range without refueling is more than 7,500 miles (12,000 kilometers), and its top speed is nearly 600 miles (970 kilometers) per hour. American bombers also include the B-1, which is smaller than a B-52 but carries a heavier bomb load. A third type of bomber, the B-2 "stealth" bomber, is a sleek plane designed to be nearly invisible to radar.

Fighters shoot down enemy aircraft and attack ground targets. They are smaller and generally faster than bombers. However, many fighters perform bombing missions. In fact, the leading precision bombers in the Persian Gulf War were F-117, F-111, and F-15E fighters. The F-117 "stealth" fighters penetrated heavy air defenses around Baghdad, Iraq, without being hit. The two-seat F-15E lacks the "stealth" of the F-117, but it is faster and can reach a speed of *Mach 2.5.* Mach 2.5 is 2.5 times the speed of sound. Sound travels about 760 miles (1,220 kilometers) per hour at sea level. Equally fast is the single-seat F-15C, which has been the Air Force's best fighter for shooting down enemy aircraft. Lighter and slower than the two-engine F-15 is the single-engine F-16, which can be used in air-to-air combat or against ground targets. The Air Force's newest fighter, the F-22, combines stealth and speed.

Other aircraft include attack and reconnaissance planes, tankers, and transports. Attack planes, such as the A-10, are designed to provide low-flying air support for ground troops, particularly against armored targets. Reconnaissance planes observe and photograph enemy forces and installations. Tanker aircraft refuel other planes in flight.

Transport aircraft carry personnel and equipment and can evacuate wounded soldiers in battle. The C-5 Galaxy can carry tanks or helicopters. The C-5 and the smaller C-141 can fly long distances. The C-17 can carry a bigger load and land on a shorter runway than the C-141 can. The C-130 Hercules is used on shorter flights.

U.S. Air Force

A jet fighter shoots down enemy aircraft and attacks ground targets. This fighter, the single-seat F-15 Eagle flies at more than twice the speed of sound.

Missiles are a major weapon of the U. S. Air Force. They can be equipped with a conventional or nuclear warhead.

Surface-launched missiles are fired from the ground at enemy ground or air targets. The largest of these are intercontinental ballistic missiles (ICBM's), which can travel from one continent to another. The Minuteman ICBM can carry 3 nuclear warheads. The Peacekeeper can carry 10 and is more accurate than the Minuteman.

Air-launched missiles are carried by bombers and fighters. *Air-to-ground missiles* (AGM's) are fired at targets on the ground. The Maverick is an AGM guided by a television or *infrared* (heat) image of a target on the ground. Other AGM's include the *H*igh-speed *A*nti-*R*adiation *M*issile (HARM) and the Shrike, which destroy enemy radar by following the radar signal to its source. *Air interceptor missiles* (AIM's) are used against enemy planes. The *A*dvanced *M*edium-*R*ange *A*ir-to-*A*ir

U.S. Air Force

A-10 Thunderbolt attack planes provide low-flying air support for ground troops, especially against armored targets. The single-seat planes are armed with guns and carry bombs.

Different types of U.S. Air Force planes carry out various missions. The KC-10 tanker refuels other planes in flight. The B-2 "stealth" bomber is designed to avoid detection by radar. The F-22 combines stealth and speed. The F-16 Fighting Falcon fighter is armed with guided missiles. The AWACS airplane can use its radar dome to detect aircraft and missiles. The C-5A Galaxy transport carries tanks and other heavy equipment.

Missile (AMRAAM) and the Sparrow are AIM's guided by radar. Another AIM called the Sidewinder seeks the heat of the enemy aircraft's engine.

Organization of the Air Force

The Department of the Air Force operates under the secretary of the Air Force, a civilian directly responsible to the secretary of defense. The chief of staff, a four-star general, is the top military officer of the Air Force. However, the chief of staff does not command the Air Force in wartime.

When Air Force units go to war, they are part of joint commands that include all branches of the armed forces. The Air Force chief of staff and his or her subordinates are known formally as Headquarters United States Air Force and informally as the *air staff.*

The Air Force has a headquarters at the Pentagon Building near Washington, D.C., and eight major commands. These units can be roughly grouped into *combat commands* and *support commands.*

Combat commands provide forces that carry out the fighting assignments of the Air Force. A four-star general usually heads a major command. These major commands are divided into successively smaller units called *air forces, wings,* and *squadrons.* A squadron usually has 20 to 25 aircraft.

In peacetime, all combat-ready missiles, bombers, fighters, attack aircraft, and reconnaissance aircraft of the active Air Force belong to one of five commands. They are the Air Combat Command, headquartered at Langley Air Force Base, Virginia; Pacific Air Forces, headquartered at Hickam Air Force Base, Hawaii;

United States Air Forces in Europe, headquartered at Ramstein Air Base, Germany; Air Force Special Operations Command, headquartered at Hurlburt Field, Florida; and Air Force Space Command, headquartered at Peterson Air Force Base, Colorado.

These Air Force combat commands make their forces available in wartime to joint commands. Joint commands include the Central Command for war in the Middle East and the Strategic Command for nuclear war. Air Combat Command was set up in 1992 by merging much of the Strategic Air Command with the Tactical Air Command. Air Force Special Operations Command has helicopters and *gunships* (airplanes or helicopters armed with guns). Air Force Space Command, a part of NORAD, has intercontinental ballistic missiles. The command also controls satellites and ground radar sites.

Support commands help the combat commands of all the services. Air Mobility Command transports troops and supplies and also extends the range of bombers and fighters by refueling them in the air. This command was formed in 1992 when its predecessor, Military Airlift Command, gained most of the air refueling aircraft that had belonged to the Strategic Air Command. The Air Force Materiel Command, formed in 1992, buys planes, missiles, and supplies. In 1993, the Air Training Command and the Air University joined to form the Air Education and Training Command.

Components of the Air Force

The regular Air Force supplies the professional core of Air Force personnel. Its size is fixed by Congress. Regular Air Force personnel include regular officers

who have graduated from an officer training program and regular airmen who enlist in the service.

Air Force reserves provide additional personnel and aircraft in times of emergency. Even in times of peace, most junior Air Force officers on active duty are reservists, and reserve units perform important functions, such as air transport.

The Ready Reserve consists of units and individuals trained and equipped to be called to duty in any emergency. The Standby Reserve includes personnel who can be called to duty in time of war. The Air National Guard is administered by the individual states, but can be called to duty by the president in emergencies.

Civil Air Patrol (CAP) is a civilian auxiliary of the Air Force. It trains young people in the science of aviation and conducts search and rescue missions.

History

United States military leaders sent up balloons to observe the enemy during the American Civil War (1861-1865) and the Spanish-American War (1898). But military officials did not begin to consider the airplane an important weapon until early in World War I.

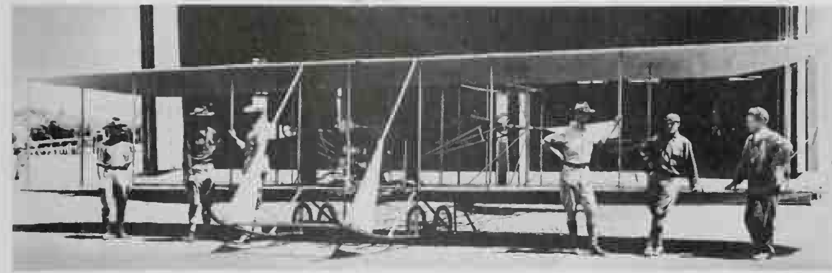
Early years. On Dec. 17, 1903, two brothers, Wilbur and Orville Wright, flew the first successful engine-powered airplane to carry a pilot. In early 1905, the Wright brothers offered to sell planes to the U.S. government, but the government did not take them seriously at first. Finally, in 1907, President Theodore Roosevelt showed interest in the airplane. That year, an Aeronautical Division was established in the office of the chief signal officer of the U.S. Army to look into the new "air machines."

The Army bought its first airplane from the Wright brothers in 1909. In 1911, Congress appropriated the first funds for aviation—$125,000. However, by 1914, when World War I broke out in Europe, the United States Army's air force owned only five planes.

The airplane's military role had grown much faster in Europe. Germany had about 250 planes. France, Russia, and the United Kingdom each had more than 100.

World War I pitted France, Russia, the United Kingdom, and other Allies against the Central Powers, including Germany and Austria-Hungary. Under the pressure of war, the European nations' air forces grew rapidly to several thousand airplanes. When the United States entered the war in April 1917, the Army had fewer than 300 training planes and no combat planes. Only American pilots who already had been flying in British and French units had significant combat experience. The Lafayette Escadrille, a French squadron which included some American pilots, already boasted several *aces,* aviators who had shot down at least five enemy aircraft.

Not all aircraft in the war were planes. Observation balloons were used for reconnaissance. Huge, *dirigible* (steerable) airships—most notably the German zeppelins—could drop bombs. See **Airship**.



At the start of the war, opposing armies used planes only to scout out enemy positions. Enemy pilots waved to each other when they passed in the sky. But soon they began to carry pistols and rifles and took potshots at each other. In 1915, a Dutch engineer, Anthony H. G. Fokker, perfected a machine gun that could fire between the revolving propeller blades. He transformed aerial warfare by making the airplane a true fighting machine. Now pilots sought enemy planes and tried to destroy them in airborne battles called *dogfights.*

Most of the airplanes used in World War I were small wood and canvas *biplanes* that had one wing above and one below the open cockpit. Plane design improved rapidly during the war. In 1914, most machines could fly only about 75 miles (120 kilometers) per hour. By 1918, planes were flying at 120 miles (190 kilometers) per hour.

As planes improved, pilots began to use them on bombing missions. At first, the pilot carried a sack of bombs in the cockpit and simply dropped them over the side. Later, mechanical devices released the bombs from under the fuselage. American pilots flew mostly French-built planes, such as Spads, Salmsons, and Nieuports. The United States produced a version of the British de Havilland D.H.4, though most of these planes did not reach the front lines. The United States entered the war with almost no airpower, but Congress quickly appropriated $640 million for military aviation. Flying schools trained 8,688 flying cadets. Another 1,800 were trained in Europe. The 94th Pursuit Squadron entered combat in April 1918. American pilots destroyed about 750 enemy planes and 70 balloons. The leading Ameri-

Important dates in Air Force history

1907 The Army set up an Aeronautical Division in the Office of the Chief Signal Officer.
1909 The Army bought its first airplane from the Wright brothers.
1914 The Aviation Section of the Signal Corps took charge of aviation operation and training.
1917 The First Aero Squadron arrived in France during World War I.
1926 Congress established the U.S. Army Air Corps.
1940 President Franklin D. Roosevelt requested 50,000 planes for the Army and Navy.
1941 Congress set up the Army Air Forces.
1945 A B-29 dropped the first atomic bomb used in warfare, on Hiroshima, Japan.
1947 The United States Air Force was created as a separate service.
1947 Captain Charles E. Yeager piloted an X-1 rocket-powered aircraft through the sound barrier.
1948 The Berlin Airlift began.
1950 The U.S. Air Force was ordered into action in Korea. Dogfights between jet fighters occurred for the first time.
1957 The Air Force successfully fired its first intercontinental ballistic missile (ICBM).
1959 The U.S. Air Force Academy graduated its first class.
1962 Air Force U-2 reconnaissance aircraft took photographs indicating that Soviet ballistic missiles were being installed in Cuba.
1965 Air Force and Navy fighter planes bombed North Vietnam to begin Operation Rolling Thunder.
1968 The C-5 Galaxy jet transport, the world's largest aircraft at the time, made its first flight.
1971 Jeanne M. Holm became the first woman in the Air Force to be promoted to the rank of general.
1976 Women were admitted to the U.S. Air Force Academy for the first time.
1986 Air Force F-111's bombed the headquarters of Libya's leader Muammar al-Qadhafi.
1988 The Air Force unveiled its "stealth" bomber and fighter planes designed to be nearly invisible to radar.
1991 The Air Force helped drive Iraqi forces out of Kuwait during the Persian Gulf War.
1995 The Air Force helped end a war between Bosnian Serbs and government forces in the former Yugoslav republic of Bosnia-Herzegovina.

U.S. Air Force

The first U.S. Army plane, shown here, was built by the Wright brothers in 1909. The aircraft, which cost $30,000, flew 42.5 miles (68.4 kilometers) per hour in a record flight that lasted 1 hour 12 minutes 40 seconds.

can ace, Captain Eddie Rickenbacker, shot down 22 enemy planes and 4 balloons. The Allies won the war.

Between world wars. The most prominent American air combat leader of World War I was Brigadier General Billy Mitchell. In September 1918, Mitchell had commanded nearly 1,500 American, British, French, and Italian aircraft during the Battle of St.-Mihiel in France. The air assault had helped Allied ground forces win an easy victory at St.-Mihiel.

Mitchell's wartime experience convinced him that air units needed to be independent of ground units so that airpower could be concentrated where it was most needed. In July 1921, he demonstrated the power of the airplane by sinking a former German battleship with aerial bombs. Mitchell's criticism of the government's defense program was so outspoken that he was court-martialed for insubordination. He chose to resign from the Army rather than accept a five-year suspension. In 1946, after developments had confirmed many of Mitchell's ideas, he was awarded the Medal of Honor, the nation's highest military decoration.

The Air Service was renamed the Army Air Corps in 1926. In 1931, the first all-metal bomber was built. In 1935, the Army tested the first B-17, the Flying Fortress that would be important in World War II.

World War II was a huge war in which Germany, Italy, Japan, and other Axis powers fought the Allies, who included Canada, China, the Soviet Union, and the United Kingdom. The U.S. Army Air Forces (AAF) was formed in 1941. The United States entered the war in December of that year, after Japan attacked the U.S. naval base at Pearl Harbor, Hawaii. By the time of the attack, the United States had begun a program of building planes and training pilots.

General Henry H. "Hap" Arnold was the first commander of the AAF. Under Arnold, the AAF grew to its top strength during World War II of 2,411,000 members and 80,000 planes. Aircraft used by the AAF during World War II included the P-51 Mustang long-range fighter and such bombers as the B-17, the B-24 Liberator, the B-25, and the B-29.

During the war, the AAF dropped more than 2 million tons (1.8 million metric tons) of bombs and destroyed over 40,000 enemy planes. The most destructive raids were the firebombing of Tokyo in March 1945 and the atomic bombing of Hiroshima in August 1945. The Tokyo raid killed an estimated 80,000 to 125,000 people, and the bombing of Hiroshima killed an estimated 70,000 to 100,000 people. The fact that a single atomic bomb could destroy a large city made nuclear weapons a dominating factor in U.S. military planning.

The AAF lost about 23,000 planes, about half of them in combat. Others were lost in training or other noncombat operations. About 88,000 U.S. Army airmen died in the war, which ended in an Allied victory.

Separate Air Force. On Sept. 18, 1947, Congress created the United States Air Force as an equal partner with the Army and Navy. It also established the Department of the Air Force. Stuart Symington became the first secretary of the Air Force, and General Carl Spaatz became the first Air Force chief of staff.

The Berlin Airlift was the first big job of the new Air Force. After World War II, the Western Allies occupied western Germany, and the Soviet Union occupied the east. Berlin, in the east, was divided into Allied-occupied West Berlin and Soviet-occupied East Berlin. On June 26, 1948, Soviet troops blockaded all ground routes through the Soviet zone of occupation to West Berlin, stopping all food and supplies. The Air Force, with British and French units, supplied the city by air. Soon Allied planes were landing at Tempelhof airport every $3\frac{1}{2}$ minutes. During the 462 days of "Operation Vittles," as U.S. airmen called it, Allied planes flew 277,000 flights carrying about 2,325,000 tons (2,109,000 metric tons) of supplies into West Berlin.

The Korean War (1950-1953) was a local war in Korea. The United States and other members of the United Nations aided South Korea, and the Soviet Union and China assisted North Korea. The war brought the first dogfights between jet fighters. In November 1950, Air Force F-86 fighters clashed with Soviet-made MiG fighters near the Chinese border along the Yalu River. Air Force pilots called this area "MiG Alley." They shot down 10 times as many jets as they lost there. When the Korean War ended, the Air Force had downed about 900 enemy planes and had lost 139 of its own planes in aerial combat. The Korean War ended without either side winning a complete victory.

The nuclear Air Force. After Korea, the Air Force found itself undergoing rapid change. It soon had thermonuclear hydrogen bombs thousands of times more powerful than the atomic bombs that ended World War II. Propeller aircraft rapidly became obsolete for most jobs. Newer planes, such as the B-52 bomber, had jet engines and carried nuclear weapons. Intercontinental ballistic missiles could be launched from the United States and the Soviet Union.

The Vietnam War (1957-1975) was a drawn-out conflict in Southeast Asia. In that war, the United States supported South Vietnam, and the Soviet Union and China backed North Vietnam and the Viet Cong rebels of South Vietnam. From 1961 to 1973, the United States dropped a much greater tonnage of conventional bombs in Southeast Asia than had been dropped by

both sides in World War II. Most of this bombing was conducted in the jungles of South Vietnam by B-52's and fighter aircraft against Communist rebels and their North Vietnamese allies. The simultaneous bombing of North Vietnam was done mostly by F-105 and F-4 fighters. Before the end of the war, the Air Force had developed laser-guided bombs, which rarely missed their targets. The war ended with a North Vietnamese and Viet Cong victory.

The Persian Gulf War. After Iraq occupied Kuwait in August 1990, the U.S. Air Force began its most extensive airlift. In six months, the Air Force transported more than 577,000 tons (523,000 metric tons) of supplies and 498,000 military passengers as far as 7,000 miles (11,000 kilometers) to points in the Middle East. After the war began in January 1991, the Air Force flew more than 37,000 combat sorties and lost only 14 aircraft. In their first extensive use, 42 F-117 "stealth" fighter-bombers dropped hundreds of laser-guided bombs without losing a plane. The air assault so devastated the Iraqis that they surrendered in February.

The Balkans. In 1991, a war began in Bosnia-Herzegovina between Bosnian Serb rebels and the country's government, which was dominated by Bosnian Muslims. The war continued for several years. In 1995, the North Atlantic Treaty Organization (NATO) intervened. As part of the NATO operation, the U.S. Air Force attacked Bosnian Serb forces to help provide relief to Bosnian Muslims under siege. Later that year, the groups involved in the conflict agreed to a peace treaty. In 1999, the Air Force participated in NATO air strikes against Serbia to end Serbian attacks on ethnic Albanians in its province of Kosovo. Wayne Thompson

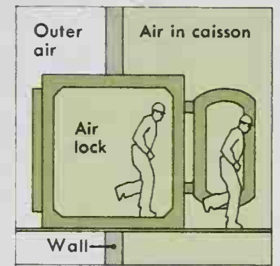
Air Line Pilots Association is the largest labor union and professional organization of airline pilots in North America. It represents more than 60,000 pilots for nearly 50 United States and Canadian airlines with scheduled flights. The association seeks to improve pay, working conditions, seniority rights, pensions, and other benefits for airline pilots. It also establishes standards for safety, aircraft performance, accident investigations, flight operations, and security.



The association was founded in 1931. Its full name is Air Line Pilots Association, International. It is affiliated with the American Federation of Labor and Congress of Industrial Organizations (AFL-CIO). Headquarters are in Washington, D.C.

Air lock is a device that permits people or materials to pass in or out of a structure called a *pneumatic caisson.* The caisson contains compressed air. Air locks are used in digging underwater tunnels or other projects that require caissons. Air pressure in the caisson balances outside water pressure, keeping water out of the working area. Caissons cannot be opened directly to the outer air because the air pressure in the caisson is much

How an air lock works

WORLD BOOK illustration by David Cunningham

Air locks enable people to enter caissons containing compressed air. When a person enters an air lock, *left,* its air pressure is the same as that outside. Air pressure in the air lock is slowly increased, *right,* to equal that inside the caisson. This action permits a person to enter the caisson without danger.

greater than the pressure of the outer air. All movements to and from the caisson must take place through an air lock. This is a large airtight chamber equipped with valves. Compressed air is forced into the air lock through these valves until the pressure within the air lock equals the pressure in the caisson. The valves are also used to withdraw compressed air from the air lock until its pressure equals the pressure of the normal outside air.

To enter the caisson, the workers first step into the air lock. Compressed air holds the inner door of the air lock tightly shut. The outer door is then closed, and compressed air slowly introduced. When pressures within the air lock and the caisson are the same, the inner door may be opened into the caisson. When workers leave the caisson, pressure in the air lock is reduced to normal, and the workers may then go out. This lowering of the air pressure, or *decompression,* must be done slowly. If the pressure drops too rapidly, the workers may develop a painful and dangerous condition called *bends.* Separate air locks are usually provided for people and for materials. A third air lock is often added to permit rapid escape in emergencies. Larry W. Mays

Air pollution occurs when wastes dirty the air. People produce most of the wastes that cause air pollution. Such wastes can be in the form of gases or *particulates* (particles of solid or liquid matter). These substances result chiefly from burning fuel to power motor vehicles and to heat buildings. Industrial processes and the burning of garbage also contribute to air pollution. Natural *pollutants* (impurities) include dust, pollen, soil particles, and naturally occurring gases.

The rapid growth of population and industry, and the increased use of automobiles and airplanes, have made air pollution a serious problem. The air we breathe has become so filled with pollutants that it can cause health problems. Polluted air also harms plants, animals, building materials, and fabrics. In addition, it causes damage by altering the earth's atmosphere.

The damage caused by air pollution costs the people of the United States billions of dollars each year. This includes money spent for health care and increased maintenance of buildings. Air pollution also causes damage to the environment that cannot be reversed.

Chief sources of air pollution

People depend on the atmosphere to dilute and remove pollutants as they are produced. But weather conditions called *thermal inversions* can trap the pollutants over a certain area until they build up to dangerous levels. A thermal inversion occurs when a layer of warm air settles over a layer of cool air that lies near the ground. This condition traps the impurities and prevents them from rising until rain or wind breaks up the layer of stationary warm air.

Forms of transportation, such as automobiles, airplanes, ships, and trains, are the leading source of air pollution in the United States, Canada, and most other industrial nations. The major pollutants produced by these sources are carbon monoxide, carbon dioxide, *hydrocarbons* (compounds of carbon and hydrogen), and *nitrogen oxides* (compounds of nitrogen and oxygen). Nitrogen oxides can react with hydrocarbons in the presence of sunlight to produce a form of oxygen called *ozone.* Ozone is the chief component of photochemical smog, which is a common form of air pollution (see Smog).

Fuel combustion for heating and cooling homes, office buildings, and factories contributes significantly to air pollution. Electric power plants that burn coal or oil also release pollutants into the atmosphere. The major pollutants from these sources are nitrogen oxides, sulfur oxides (compounds of sulfur and oxygen), particulates, and carbon dioxide.

Industrial processes produce a wide range of pollutants. Oil refineries discharge ammonia, hydrocarbons,

Air pollution is a serious problem in many of the world's large cities. Heavy concentrations of air pollutants, which are often in the form of smog, settle over a city, creating a health hazard for its people.

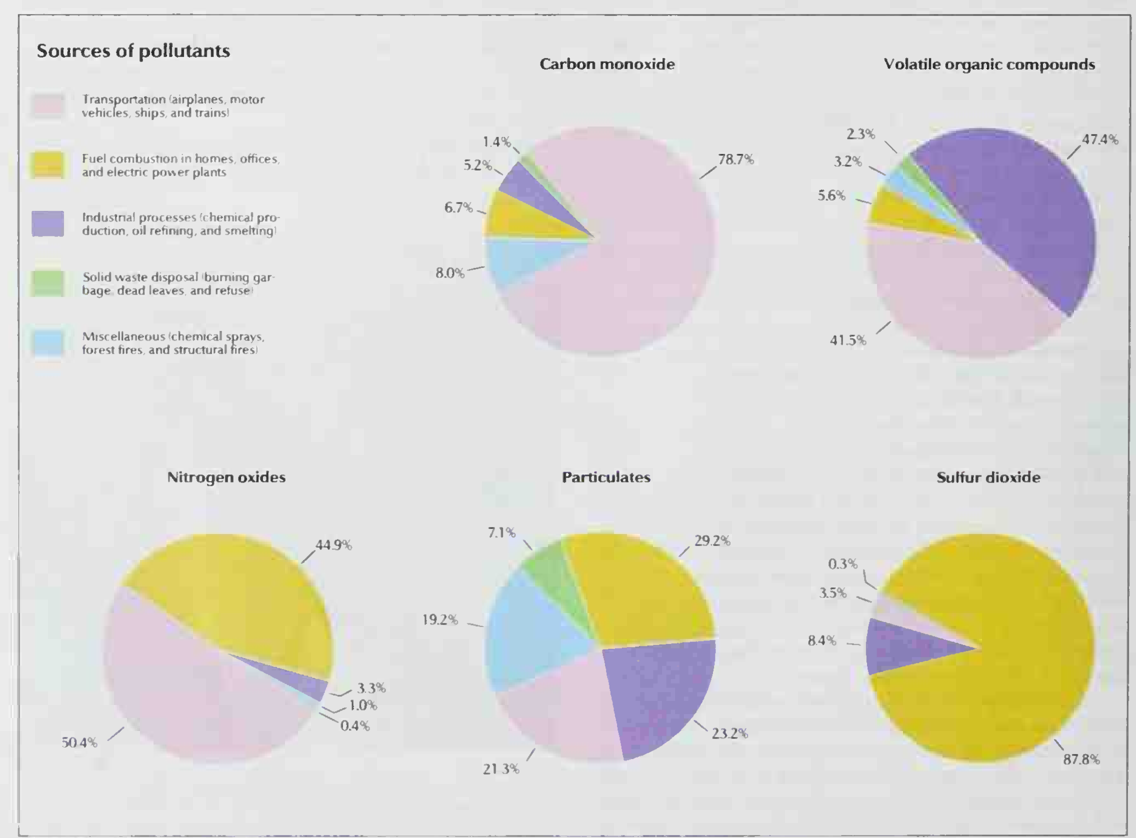
organic acids, and sulfur oxides. Metal smelting plants give off large amounts of sulfur oxides and particulates containing lead and other metals. Plants that make aluminum expel fluoride dust. By 1996, most industrialized countries, including the United States, had ended production of *chlorofluorocarbons* (CFC's), compounds of chlorine, fluorine, and carbon. However, many older refrigerators and air conditioners produce CFC's during normal operation.

Burning of solid wastes often creates a very visible form of air pollution—thick, black smoke. It also produces invisible pollution in the form of toxic chemicals called *dioxins*. Many cities and towns enforce bans on the burning of garbage, leaves, and other refuse.

Other sources of pollution include chemical sprays and organic chemicals used to start fires on charcoal grills. Forest fires and structural fires also contribute to air pollution. In rural areas and in developing countries, the burning of forests and grasslands to clear areas for farming is a major source of air pollution.

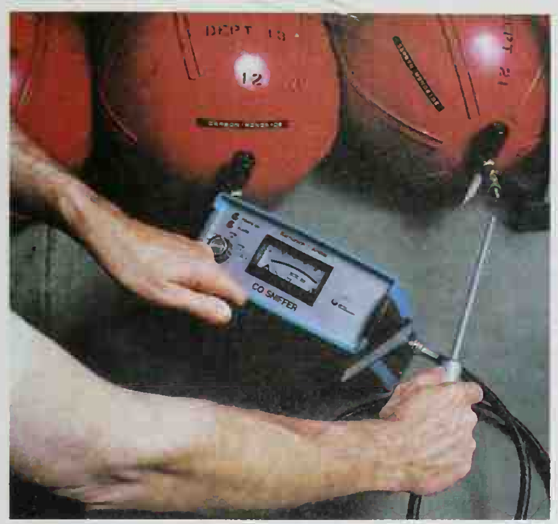
Natural sources also contribute to air pollution. Volcanoes emit large amounts of sulfur oxides and particulates. Microbes in the digestive tracts of cattle and in rice fields break down plant materials and release an odorless gas called *methane,* a type of hydrocarbon.

Indoor air pollution occurs when energy-efficient houses and office buildings trap pollutants inside. As a result, some pollutants found outdoors are found indoors in even higher concentrations. Some plastic products, processed wood products, paints, and adhesives can give off hydrocarbons. Many cleaning products emit poisonous gases such as ammonia and chlorine. Soil and rocks release an odorless gas called *radon* into the atmosphere. The gas enters buildings through cracks in the foundation (see Radon).



Effects of air pollution

Health. When people breathe polluted air, the impurities can irritate their air passages and their lungs. Particulates often remain in the lungs, and they can worsen such respiratory ailments as asthma and bronchitis. Radon can cause lung cancer if inhaled in large quantities. Certain chemical compounds can cause cancer and birth defects. Ozone reduces resistance to colds and pneumonia and can aggravate emphysema. Carbon monoxide interferes with the transfer of oxygen from the lungs to body tissues.



In London in 1952, about 4,000 people died of respiratory diseases during a "killer smog." More than 600 people died as a result of thermal inversions that occurred

Major air pollutants and their sources

Most air pollution results from human activity. These pie graphs represent the total emissions of each of the five major air pollutants in the United States in 1996. The legend identifies the sources of air pollution by color. Each graph shows how much each source contributed to that kind of air pollution. All natural sources of air pollution are included in "Miscellaneous," as well as other sources.

Figures are for 1996. Source: U.S. Environmental Protection Agency.

A carbon monoxide detector is used in manufacturing facilities to test for leakage from tanks that store the gas. Carbon monoxide has many uses in industry, but it is a deadly poison.

© Chris Jones, The Stock Market

A platinum catalyst scrubber is used in an industrial smokestack to remove pollutants before they can be released into the air. The pollutants stick to metal oxide crystals in the scrubber.

in New York City in 1953 and 1963. Today, such extreme events are rare in many countries because of government *emission standards,* which limit the amounts of pollutants that factories and other sources may release. However, air pollution still contributes to a large number of deaths each year.

Agriculture. Air pollutants can stunt the growth of crops, harm livestock, and destroy crops. Such damage can prove costly to farmers. Forests also have been damaged by air pollution.

Atmosphere. Some pollutants are not poisonous but can cause damage by altering the earth's atmosphere. For example, the amount of carbon dioxide in the atmosphere has been increasing since the early to mid-1800's, chiefly as a result of the burning of coal, oil, and other carbon-containing fuels. Carbon dioxide allows sunlight to reach the earth and warm its surface, but it prevents some surface heat from escaping out of the atmosphere. This *greenhouse effect* can produce significant climatic changes, which will result in great environmental challenges. See Greenhouse effect.

CFC's break down the layer of ozone in the earth's upper atmosphere. This layer protects plants and animals from harmful ultraviolet rays (see **Ozone**).

Other effects. Most materials deteriorate faster when exposed to the pollutants present in the air. Concrete and stone are dissolved by air pollutants. Metals corrode faster than usual. Plastics, rubber, and fabrics are also damaged by air pollutants.

Air pollution is closely related to other forms of pollution. Sulfur dioxide and nitrogen oxides can react with water droplets in the air to produce acid rain. Acid rain pollutes lakes and streams and, in high concentrations, can harm soil fertility (see Acid rain).

Control of air pollution

In the United States, all levels of government—federal, state, and local—have passed laws designed to control pollution. Congress passed the Air Quality Act in 1967. Under this act, the federal government sets goals called *air quality standards* for achieving cleaner air. The states must enforce air pollution controls to meet the goals. When states fail to enforce the regulations, the federal government can act against polluters by imposing fines.

The Clean Air Act of 1970, and its amendments, have set strict standards for air quality and emissions. It has required fuel producers to develop cleaner-burning fuels. It also requires automobile manufacturers to equip new vehicles with pollution control devices called *catalytic converters.* In addition, the smokestacks of many electric power plants, incinerators, and factories must have *scrubbers* installed to remove pollutants before they can reach the air. New standards will remove most sulfur from fuels and reduce emissions of particulates. However, industry groups have repeatedly opposed stricter standards.

States may set stricter air standards than the federal government requires. Since 1970, California has set the strictest standards for motor-vehicle emissions. Several states require that a certain percentage of vehicles sold annually must be non-polluting.

Efforts to control air pollution in the United States have been generally successful. Between 1970 and 1997, federal regulation resulted in a 98-percent reduction in lead emissions. During this same period, pollution by dust particles decreased by 75 percent. Pollution by sulfur dioxide decreased 35 percent. Both carbon monoxide and ozone emissions were reduced by more than 30 percent. Efforts to reduce nitrogen oxide pollution have met with the least success. Nitrogen oxide emissions decreased by only about 10 percent between 1970 and 1997. They increased for a number of years during this period before finally decreasing.

In other countries. The lack of controls on automobile emissions in Western Europe has contributed to extensive damage to forests there. Countries in Eastern Europe have lacked pollution controls altogether and as a

result, have suffered enormous environmental damage.

Air rights are the rights to use the space above a piece of real estate. In the United States, a person or a company that owns land also owns the air rights above it. The use of air rights increases the value of land. For example, some companies construct buildings in leased air rights over railroad tracks. In this way, companies use space that would otherwise be wasted.

Since the early 1900's, many large buildings have been constructed in air rights over railroad tracks. These buildings include the Merchandise Mart in Chicago and the Terminal Tower in Cleveland. Buildings constructed over railroad tracks must have a large chimney or airway to carry off the smoke and foul air of the trains below. The buildings also must have special sound insulation to reduce the noise from the trains.

Air rights over highways can provide additional space for apartment buildings, office buildings, parking garages, and schools. In some states, the law does not clearly determine who owns the air rights over highways and railroad tracks. As a result, the sale and use of these air rights have been limited. Zoning laws that limit building height also affect the use of air rights.

Landowners cannot prevent aircraft from flying over their land at a legal height. But they have the right to protection from noise caused by aircraft. In the late 1960's, the Federal Aviation Administration began to set limits for aircraft noise levels.

Every nation owns the air rights over its territory. A country may control this air space and deny the aircraft of other nations the right to fly over its territory. But international law has not yet determined if such air rights extend into outer space. Jean Appleman

Its headquarters are located in Washington, D.C.

Critically reviewed by the Air Transport Association of America

Air turbulence is a disturbance of the air that is often felt by the passengers and crew of aircraft. Air turbulence may produce only a slightly bumpy ride. But in some cases, luggage and even passengers have been tossed about the cabin.

A major source of air turbulence is *convective heating.* This phenomenon begins when the sun heats the ground. The ground, in turn, heats the air just above it. Because warm air is less dense than cool air, parcels of warm air rise in a *convection current.* Cooler air then moves downward and inward, filling the space beneath the rising air. We can see an up-and-down movement of air parcels in puffy cumulus clouds. Air travelers who fly through even a small cumulus cloud usually feel some turbulence.

Much air turbulence is not readily visible and so is known as *clear-air turbulence.* Convective heating can create clear-air turbulence where there is not enough moisture to form clouds. Clear-air turbulence also occurs at extremely high altitudes, where clouds are rarely present.

An example of turbulence at high altitudes is a disturbance created by a *jet stream.* Jet streams are bands of fast-moving air that circle the earth at altitudes of about 30,000 to 45,000 feet (9,000 to 15,000 meters). Airflow in the core of the jet stream is usually smooth. However, near the stream's outer edge, the high-speed air rubs against the surrounding low-speed air. This interaction creates pockets of air turbulence.

In the Northern Hemisphere, aircraft flying in an easterly direction frequently ride in a jet stream to reduce travel time. As an airplane crosses the stream's outer boundary, the occupants of the craft usually feel turbulence.

Air turbulence is also associated with *weather fronts,* narrow zones between huge volumes of air that differ in

temperature or humidity. These air masses move over the earth's surface much like blobs of molasses on an apple. Where air masses bump and rub against one another, pockets of air turbulence form.

Airflow over mountain ranges creates air turbulence at virtually all altitudes. Certain cloud formations sometimes indicate the presence of low-altitude disturbances. But clear-air turbulence also occurs over mountain ranges. The movement of an air mass over a range may create several disturbances at the same time. This turbulence can often be felt at altitudes as high as 60,000 feet (18,000 meters). Brian M. Argrow

Airbag. See Air bag.

Airborne troops are soldiers trained for assault by air. They may be dropped to the ground by parachute, or transported to combat areas by airplanes. Airborne troops of the United States Army are volunteers. The chief center for training U.S. airborne troops is at Fort Bragg, North Carolina.

Volunteers must undergo a difficult three-week training course. In combat, airborne troops land behind enemy lines, blow up bridges, destroy communications, and cut off supplies and reinforcements. They often take the enemy by surprise and engage in fierce hand-to-hand fighting. Airborne troops carry heavy packs of equipment, including an automatic rifle, a machine gun, grenades, a medical kit, and radio equipment.

In World War II, both the Allies and the Germans used airborne troops. The Germans first employed sky soldiers in the Netherlands in 1940 and in capturing the island of Crete in 1941. The Allies made the most effective use of paratroops. They formed a complete army of sky soldiers and coordinated parachute attacks with air, land, and naval operations. United States Army paratroopers spearheaded attacks in Sicily, Normandy, and the Netherlands. In the Philippines, airborne troops recaptured Corregidor from Japanese forces.

Photri

Airborne troops drop by parachute from an airplane into a battle area or behind enemy lines.

Airborne troops have taken part in all major military operations since World War II. United States airborne troops are often called *paratroops, paratroopers,* and *sky soldiers.* David R. Kiernan

Airbrush is a tool used by photographers and commercial artists to apply color or shading to drawings, prints, and photographs. Photographers find it useful to bring out highlights and to supply backgrounds. The airbrush looks something like a pencil. It has a length of tubing at one end and a fine nozzle at the other. An electric pump or tank with a pressure gauge supplies a current of compressed air. The air enters the nozzle through the tubing and sends a stream of fine particles of liquid coloring matter out through the nozzle. The artist controls the air pressure by means of a valve to create different effects.

Kongsgaard Studio (WORLD BOOK photo by Steinkamp/Ballogg)

The airbrush blows out a mist of coloring matter that creates images with delicate tones and a smooth-looking surface.

The *spray gun* is a tool that works in the same way as an airbrush, but it takes less skill to operate. Painters use it to apply a coat of paint, varnish, shellac, and other finishing materials to all types of manufactured articles.

Aircraft. See Aircraft, Military; Airplane; Airship; Autogiro; Balloon; Glider; Guided missile; Helicopter; Rocket; V/STOL.

Aircraft, Military. Military aircraft are airplanes, helicopters, and other flying machines used for military purposes. Most military aircraft are operated by pilots. But aircraft called *unmanned aerial vehicles* (UAV's), which carry no crew, are guided by electronic devices.

Armed forces use military aircraft for a wide variety of tasks in both combat and peacetime. During a war, these aircraft attack enemy forces, protect and transport troops and supplies, defend territory, and carry out many other types of missions. Peacetime uses include rescue operations and scientific expeditions.

Military aircraft range from UAV's the size of small

Military aircraft, such as the United States aircraft shown here, are designed to perform various tasks. For example, bombers attack targets with bombs, missiles, rockets, and other weapons. Tankers refuel aircraft in flight. Reconnaissance aircraft observe and photograph enemy forces and bases. Transport helicopters are used to carry cargo.

model airplanes to huge transport planes that carry tanks and trucks. Their speeds also vary greatly, reaching more than 2,000 miles per hour (mph), or 3,200 kilometers per hour (kph), for some jet planes. Some aircraft are designed for specialized duties. For example, some military planes take off and land vertically, enabling them to operate from ships and rough terrain. Others can fly at extremely high altitudes to escape enemy missiles or at low altitudes to avoid detection by radar.

Types of military aircraft

Most military aircraft are *fixed-wing aircraft* (airplanes) or *rotary-wing aircraft* (helicopters). They are classified by their function. Those that can perform more than one type of mission are designated by their original or principal use. Military planes include (1) bombers, (2) fighters, (3) reconnaissance aircraft, (4) transports, (5) tankers, and (6) special-mission aircraft. Some of these classifications are also used for helicopters.

Bombers attack targets with bombs, missiles, rockets, and other weapons. The two main kinds of bombers are *strategic bombers* and *fighter-bombers.* Most strategic bombers are large, long-range airplanes that can attack targets deep inside enemy territory. They have two or more jet engines and a crew of two to six people. One such strategic bomber, the American-made B-1B, can fly up to about 7,500 miles (12,000 kilometers) without refueling. Its top speed is *Mach 1.25,* which is $1\frac{1}{4}$ times the speed of sound. The American B-2 "stealth" bomber has special features that make it difficult to detect by radar. These features include surface materials that absorb radar energy and a winglike shape that deflects radar beams. See **Air Force, United States** (picture: B-2 "stealth" bomber).

Most fighter-bombers, also called *attack planes,* are small, short- to medium-range aircraft with one or two jet engines and a crew of one or two people. These planes are used primarily to attack ships and ground forces. One of the most advanced fighter-bombers is the American F-117 "stealth" fighter. Features much like those of the B-2 bomber make the F-117 difficult to detect by radar.

Fighters are used chiefly to intercept and attack other aircraft, but they also hit ground targets. These planes must be fast and easy to maneuver. Most fighters carry cannons, rockets, and missiles. The American F-14 Tomcat has an electronic weapons system that automatically detects and tracks enemy aircraft. It allows a pilot to fire at enemy aircraft long before seeing them. The F-14 has *variable-sweep wings,* which can be spread out or swept back according to the flight speed.

Most fighters have one or two jet engines and a crew of one or two people. Many have *swept-back wings,* which slant backward from the plane's body to the tip of the wing, or triangle-shaped *delta wings* to provide great speed. Two widely used fighters, the Russian MiG-29 and the French Mirage, can fly faster than Mach 2.

Reconnaissance aircraft are equipped with cameras or electronic sensing devices for collecting information about enemy forces. The TR-1, one of the few American reconnaissance aircraft, is used to locate enemy forces during wartime. The plane's sensing devices can detect signals from enemy radars, communications, and other electronic equipment. Some reconnaissance aircraft photograph enemy forces and bases. However, artificial satellites that orbit the earth carry out most photographic reconnaissance today.

Transports carry military personnel and equipment. Almost any aircraft can be used as a transport, but some combat situations require specially designed planes. Most such specialized transports have oversized tires on their landing gear and high-lift devices on their wings that enable the planes to use short, unpaved runways. The largest transport, the Russian Antonov An-124, can carry more than 330,000 pounds (150,000 kilograms). Some transports are equipped with guns to convert them to attack aircraft called *gunships.*

Tankers refuel other aircraft in flight. A tanker must be able to fly at the same speed and altitude as the planes it refuels. The planes approach from behind and below and pick up refueling tubes that trail from the tanker. Nearly all tankers are modified bombers, cargo aircraft, or commercial airliners. The U.S. Air Force uses the KC-135, a version of the Boeing 707 airliner, and the KC-10, a version of the McDonnell Douglas DC-10.

Special-mission aircraft include electronic support aircraft, trainers, and UAV's. Electronic support aircraft contain sensitive electronic instruments. Some of these aircraft are used to interfere with enemy radar and other electronic equipment. Others guard against air or ground attack and serve as command centers in a war. The U.S. Air Force uses the Airborne Warning and Control System (AWACS) aircraft. A radar dome on top of this plane can detect and track aircraft and missiles.

Trainers are used to train pilots and are designated by the stage of training in which they serve—primary, basic, or advanced. They range from planes with piston engines to jet aircraft that can be used for both training and combat. UAV's of various sizes are used for hazardous reconnaissance missions and as targets in combat practice.

Helicopters play an important role in military operations because they can be used in a variety of missions. They have the ability to take off and land almost anywhere, and they can hover over one spot. Helicopters serve chiefly as attack aircraft, reconnaissance aircraft,

U.S. Air Force

The French Mirage 2000 is a fighter airplane designed mainly to intercept enemy planes. The missiles attached under its wings can be fired at enemy aircraft.

U.S. Air Force

The F-117 "stealth" American fighter is designed mainly to attack ground forces and ships. Flat surfaces on its fuselage deflect radar beams, making the plane difficult to detect.

The Boeing Company

The C-17 Globemaster III is a United States transport plane. It can carry about 205 troops or 160,000 pounds (72,500 kilograms) of cargo a distance of about 2,750 miles (4,450 kilometers).

and transports. Some attack helicopters are called *helicopter gunships.* A gunship, such as the American-made AH-64 Apache, can carry cannons and missiles to attack targets on the ground and in the air. Other helicopters are specially equipped for antisubmarine warfare. The American-made OH-58 Kiowa, the British Lynx, and other small helicopters are used for reconnaissance and light transport duty. The largest transport helicopters can pick up and carry planes, tanks, or trucks by using cables suspended from the helicopters.

History

The first military aircraft were balloons filled with gas or hot air. In 1794, the French Army sent up soldiers in balloons to observe enemy troop movements. During the 1800's, most major armies set up a balloon corps.

Heavier-than-air aircraft gained military importance after 1903, when the Wright brothers made the first successful plane flight. Early planes were made of cloth, wood, and wire and had a low-powered gasoline engine. Most of these aircraft were called *biplanes* because they had two main wings, one above and one below the body of the plane. By 1914, biplanes could fly at an average of 75 mph (121 kph) and reach an altitude of about 10,000 feet (3,000 meters). Military use of the planes was limited largely to reconnaissance.

World War I (1914-1918) brought great changes in the design and performance of military aircraft. For example, the German Army used the engine-powered *airship,* a lighter-than-air aircraft, for reconnaissance and bombing missions. In addition, both sides recognized the possible advantages of using airplanes for attack as well as for reconnaissance. Engineers designed larger, more powerful planes that could carry bombs over long distances. The introduction of these bombers created a need for fighter aircraft to intercept them. As the war continued, fighters were armed with more effective weapons and became faster and easier to maneuver.

During the 1920's and 1930's, further improvements were made in military aircraft design. Biplanes were replaced by aluminum *monoplanes.* The monoplanes had one main wing, which extended outward from both sides of the body of the plane. Increasingly powerful engines and a streamlined design enabled monoplanes to

Early military aircraft

The first military aircraft were balloons used for reconnaissance. Heavier-than-air aircraft, developed during the early 1900's, played a major role in World War I (1914-1918). Some important early military aircraft are shown below. The dates indicate when the aircraft were first built.

reach speeds of more than 300 mph (480 kph).

World War II (1939-1945) sped up the development of piston-engined aircraft and marked the first use of jet planes. One of the most advanced fighters was the British Spitfire, which could fly faster than 350 mph (563 kph) and higher than 40,000 feet (12,000 meters). Late in the war, Germany began to use the Messerschmitt Me 262, the first jet to fly in combat. This plane had a top speed of almost 550 mph (885 kph).

The jet age. Aircraft technology made further rapid progress in the 1950's, 1960's, and 1970's. For example, new types of wings and other structural improvements greatly increased the speed and maneuverability of jet planes. The United States and the Soviet Union developed jet bombers that could fly nonstop from their own country to the other country in only a few hours.

At the same time, ground warfare was transformed by the wide use of helicopters. Military helicopters were introduced on a large scale in the Korean War (1950-1953), chiefly for transporting supplies and wounded troops. In the late 1950's, the use of jet engines boosted the speed and lift capacity of helicopters.

During the Vietnam War (1957-1975), the United States Army, Navy, and Air Force used helicopters for attack, reconnaissance, and transport. Helicopters were also used to rescue pilots shot down in enemy territory.

Recent developments in military aircraft include improvements in design and materials. Surfaces that deflect radar beams and materials that absorb radar energy make "stealth" aircraft difficult to detect by radar. The *supercritical wing,* which is thinner and flatter than a standard wing, increases the speed and range of planes. In some supersonic aircraft, titanium and other heat-resistant materials have replaced aluminum, which melts at speeds higher than Mach 2.5.

Length—99 ft. 11 in. (30.45 m)

Aircraft carrier is a ship used as a mobile base for airplanes. With its aircraft striking force, the carrier is the most powerful surface warship. Carriers are often called *flattops* because of their wide, flat decks. The only ships bigger than carriers are the largest oil tankers.

Aircraft carriers are equipped with only a minimum number of antiaircraft guns or defensive missiles. Carriers usually *steam* (travel) with other ships. Cruisers, destroyers, and submarines protect aircraft carriers from enemy missiles, planes, surface ships, and submarines. Such a fleet is called a *carrier task force* or *battle group.*

Airplanes take off from and land on the *flight deck.* They are repaired and stored on the *hangar deck* just below it. Large elevators move the planes from one deck to the other. The *superstructure* of the ship, called the *island,* includes the command and navigation bridges, communications equipment, radar antennas, and smokestacks, unless the ship has nuclear power. The island rises on the flight deck's *starboard side* (right side facing forward). The rest of the deck is left clear for planes. A carrier also houses maintenance shops for the planes and living quarters and *mess* (cooking and eating areas) for the pilots, air crews, and ship's crew. It has storage space for bombs, ammunition, fuel, and food.

The United States Navy operates the world's largest carrier fleet, consisting of 12 ships. The navies of Brazil, France, India, Italy, Russia, Spain, Thailand, and the United Kingdom each have at least one aircraft carrier.

Flight operations. Conventional airplanes, helicopters, and *V/STOL* (*V*ertical/*S*hort *T*ake-*O*ff and *L*anding) aircraft operate from aircraft carriers. Only the navies of Brazil, France, Russia, and the United States have carriers that launch and land conventional aircraft. The carriers operated by the navies of other nations carry only V/STOL aircraft and helicopters.

Conventional airplanes are too heavy and require too great an airspeed to take off from a carrier entirely under their own power. For this reason, they are launched by a catapult from the take-off areas (see Catapult). The carrier steams into the wind at high speed during take-offs. Wind speed plus the ship's speed helps lift the planes as they take off.

The carrier also heads into the wind when planes land. If a carrier steams at 25 *knots* (nautical miles per hour) into a wind blowing 25 knots, then the wind speed over the carrier's deck is 50 knots. A plane flying at 100 knots thus has a relative landing speed of only 50 knots. *Arresting gear,* four steel cables stretched across the rear landing area of the deck, catch a tail hook lowered from the plane. The plane is brought to a stop over a distance of about 300 feet (90 meters).

Modern carriers for conventional aircraft have angled landing sections on their flight decks. The landing section, which takes up the rear two-thirds of the deck, angles toward the carrier's *port side* (left side facing forward) and extends over the water. A plane that makes a bad approach or misses the arresting wires with its tail hook may keep going and fly off the deck. Helicopters and VTOL aircraft take off and land vertically and so require no runway.

The United States carrier fleet. Aircraft carriers are the U.S. Navy's principal warships. They carry jet fighters and jet bombers. They also have radar, reconnaissance, and tanker planes, and antisubmarine aircraft. Each carrier usually carries six helicopters.

The Navy groups its carriers by *class.* The name of each class is the name of the first ship built in that class. The four classes of carriers are, from the newest to the oldest, Nimitz, John F. Kennedy, Kitty Hawk, and Enterprise. Ships of the Nimitz and Enterprise classes are nuclear-powered. Those of the John F. Kennedy and Kitty Hawk classes are oil-powered.

The Nimitz class consists of the *Nimitz,* the *Dwight D. Eisenhower,* the *Carl Vinson,* the *Theodore Roosevelt,* the *Abraham Lincoln,* the *George Washington,* the *John C. Stennis,* and the *Harry S. Truman.* Nimitz class ships are the world's largest warships measured in *displacement tonnage.* This measurement refers to the number of long tons or metric tons of water *displaced* (occupied) by a ship. Each Nimitz class ship displaces 97,000 long tons when fully loaded. A long ton is equal to 2,240 pounds or 1.016 metric tons. Each ship is 1,092 feet (333 meters) long and has a flight deck 252 feet (77 meters) wide. Each can carry 85 aircraft and about 5,700 people.

The John F. Kennedy class consists of one ship, the *John F. Kennedy.* This ship displaces 82,000 long tons when fully loaded, and can carry 85 aircraft and about 5,600 people.

The Kitty Hawk class consists of the *Kitty Hawk* and the *Constellation.* Both ships displace 80,800 long tons when fully loaded and can carry 85 aircraft and about 5,600 people.

U.S. Navy

An aircraft carrier is a warship that serves as a mobile base for jet bombers, fighters, and other types of military planes. The nuclear-powered carrier *Carl Vinson,* shown here, is part of the *Nimitz* class of U.S. Navy carriers.

The Enterprise class consists of one ship, the *Enterprise.* This ship, which was commissioned in 1961, was the world's first nuclear-powered aircraft carrier. It displaces 89,600 long tons when fully loaded. The *Enterprise* can carry 85 aircraft and about 5,800 people.

History. Beginning in 1910, British and American pilots experimented with take-offs and landings from ships. In 1917, the *Furious,* a British Royal Navy cruiser, was outfitted with a flight deck. The first ship to have a full, unobstructed flight deck was the Royal Navy's *Argus,* completed in 1918. The first aircraft carrier in the United States Navy was the *Langley,* a converted *collier* (coal ship). It went into service in 1922. The *Ranger,* commissioned by the U.S. Navy in 1934, was the first ship built especially for aircraft.

During World War II (1939-1945), the warring nations built more than 150 aircraft carriers. They were the most important ships of the war. Planes launched from Japanese carriers attacked the U.S. naval base at Pearl Harbor, Hawaii, and the first United States air raid on Japan was made by bombers from the *Hornet.* British aircraft carriers escorted supply convoys in the Atlantic Ocean and the Mediterranean Sea, and also took part in fleet actions such as the sinking of the German battleship *Bismarck.*

After the war, many carriers were scrapped. By the 1960's, only the United States maintained a large fleet of carriers. Among these ships were those of the Forrestal class—the *Forrestal,* the *Saratoga,* the *Ranger,* and the *Independence.* The *Forrestal,* commissioned in 1955, was the first U.S. carrier to have an angled flight deck and to carry jet fighters. Forrestal class ships carried more aircraft than previous carriers, and they were sometimes called *supercarriers.* Norman Polmar

Airedale terrier, *AIR DAYL,* is the name of a breed of large terriers. It weighs 50 to 60 pounds (23 to 27 kilograms) when full-grown. Its coat of wiry hair is black or grizzled on its back, and a rich tan on the other parts of its body.

The Airedale was named for the Aire Valley in northern England. This breed was developed in England about 1880. One of its ancestors was the otter hound. The Airedale is fearless, a good watchdog, and affectionate toward its owner. It also is a good swimmer.

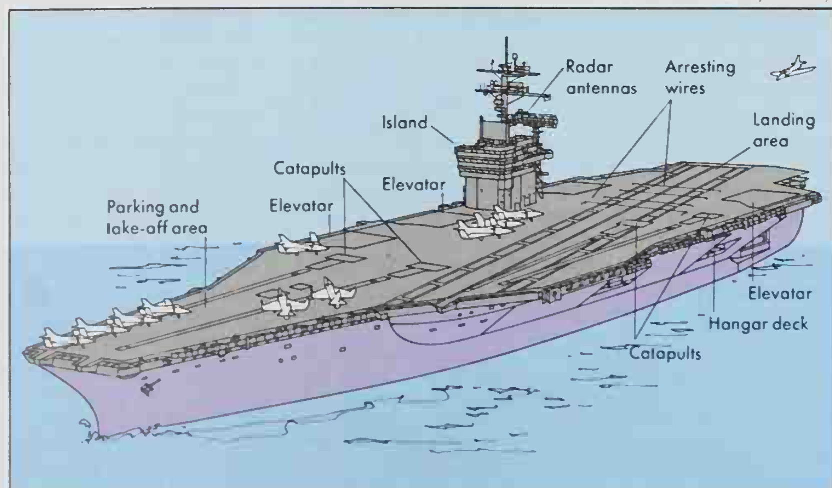
Airliner. See **Airplane** (Commercial transport planes).

Airmail is mail sent by aircraft. It is the fastest way to send packages and many other types of mail to distant places. Airliners carry the mail between large cities. Some cities offer helicopter service between central and suburban post offices. Nearly all first-class mail going more than 200 miles (320 kilometers) travels by air.

Early balloonists and pioneer airplane pilots sometimes carried airmail as stunts. Earle Ovington flew the first official airmail in the United States in 1911 between Garden City and Mineola, New York. The first continuous regular airmail service in the world started on May 15, 1918, with United States Army pilots flying between New York City, Philadelphia, and Washington, D.C.



On Aug. 12, 1918, the Post Office Department (now the United States Postal Service) began making contracts with private airlines to carry the mail. The first night airmail was flown from Omaha, Nebraska, to Chicago in 1921. Regular night airmail flights and regular transcontinental mail service began in 1924. The American Railway Express Company began shipping air express packages on airlines in 1927.

The cancellation of all airmail contracts in 1934 marked the beginning of airmail rate regulation. Rates were regulated by the Civil Aeronautics Administration (now part of the Federal Aviation Administration). The regulation of airmail rates and service ended on Dec. 31, 1984. In 1985, the U.S. Postal Service returned to contracting with a variety of both passenger and freight airlines to transport mail.

WORLD BOOK illustration by Robert Keys

Parts of an aircraft carrier

Aircraft take off from and land on the *flight deck* of a carrier. This deck has catapults and arresting wires that assist planes. Elevators move aircraft to and from the *hangar deck,* where they are stored. The *island* houses communications and radar equipment.

The Boeing Company

A giant commercial airliner can bring all parts of the world within easy reach of one another by flying hundreds of passengers long distances. The Boeing 777-300, the world's largest twin-engine passenger jet, can fly about a fourth of the way around the world without refueling.

Airplane

Airplane is an engine-driven machine that can fly through the air supported by the flow of air around its wings. Hundreds of thousands of airplanes are used throughout the world. Millions of people depend on aircraft for swift transportation. Businesses rely on quick airmail and air express service, and many industries ship their products by air. Airplanes have many other uses, from helping fight forest fires to carrying emergency aid. In addition, airplanes are a major weapon of war.

Airplanes provide the world's fastest practical means of transporting passengers and freight. Most large transport planes routinely fly 500 to 600 miles per hour (mph), or 800 to 970 kilometers per hour (kph). The fastest airplanes are *supersonic,* which means they can fly faster than sound travels. At sea level, sound has a speed of 760 mph (1,225 kph). A *supersonic transport plane* (SST) can roar through the air at about 1,350 mph (2,180 kph). Such planes carry passengers between London or Paris and New York City in less than four hours.

The contributors of this article are Drew Steketee, Senior Vice President of the Aircraft Owners and Pilots Association, and F. Robert van der Linden, Curator of Aeronautics at the National Air and Space Museum of the Smithsonian Institution. The drawings throughout this article, unless otherwise credited, were prepared for World Book *by Tom Morgan.*

Airplanes range in size from training planes, which have only two seats, to jumbo jets, which can carry hundreds of passengers. In the United States, about 90 percent of all airplanes have one or two engines and carry only a few passengers at a time. Many people use such airplanes for short business or pleasure trips.

Manufacturers build airplanes according to the principles of *aerodynamics,* the study of the forces acting on an object as it moves through the air. An airplane has wings, one or more engines, and various control surfaces. The wings extend from either side of the plane's body. The wings are *fixed*—that is, they do not move—and curved on top. As the plane moves forward, the air flowing around the curved wings creates an area of lower air pressure above the wings, resulting in a lifting force. An airplane's engines give it the power to move fast enough through the air to produce the lift needed for flight. The control surfaces are movable sections on the back edge of the wings and tail that the pilot moves to control the plane's flight path. The activity of designing, building, and flying aircraft is called *aeronautics.*

An airplane is a *heavier-than-air* aircraft, meaning it is heavier than the air it displaces. An airplane achieves

A powerful jet cargo plane can carry tons of goods nonstop for thousands of miles or kilometers. Privately operated package delivery services use planes like the one above to deliver almost any kind of merchandise within a few days to customers throughout the world.

flight in a different way than an *airship,* also called a *blimp,* which is a *lighter-than-air* aircraft. A typical airship rises and floats in the air because it is filled with a gas that is lighter than the surrounding air.

During the late 1700's, people made their first flights into the air using balloons, which were an early form of airship. After the first balloon flights, inventors tried to develop a heavier-than-air flying machine. Some inventors experimented with *gliders* (engineless planes). They studied birds' wings and discovered that the wings are curved. By building gliders with curved wings instead of flat ones, they could make the vehicles fly hundreds of feet or meters. But long-distance flight in a heavier-than-air machine did not become possible until the invention of an engine light enough but powerful enough to keep a plane in flight. The first such engines were four-stroke gasoline engines, developed during the 1880's and initially used to power bicycles, boats, and carriages.

In 1903, the brothers Orville and Wilbur Wright—two American bicycle makers—made the first successful powered airplane flights in history near Kitty Hawk,

Henley & Savage, Uniphoto

Light planes make up most of the world's privately owned airplanes. Most light planes are propeller driven, have a single engine, and are small enough to land and take off at small airports.

VIII. History

North Carolina. After the Wright brothers' success, pilots and inventors worked continually to improve airplane design. By the late 1950's, passenger planes with jet engines had brought all countries within easy reach of one another, and the world seemed much smaller than it had just a few years before.

This article provides an overview of airplanes and how they work. To learn about the aviation industry and careers in aviation, see the *World Book* article on **Aviation.**

Types of airplanes

There are many kinds of airplanes that vary greatly in size, speed, and function. Today's airplanes can be divided into five main groups: (1) commercial transport planes, (2) general aviation planes, (3) military planes, (4) seaplanes, and (5) special-purpose planes.

Commercial transport planes are large planes owned by airline companies. Most of these planes are *airliners*—planes that are designed to carry passengers and some cargo. Some commercial transports are designed to carry cargo only. The largest transport planes commonly used weigh about 400 short tons (360 metric tons) when fully loaded.

Most large airliners can carry from 100 to 250 passengers. However, some can carry more. For example, the Boeing 747 has room for over 400 passengers. It has 12 washrooms and 6 galleys and carries more than 47,000 gallons (178,000 liters) of fuel.

Most airliners routinely fly 500 to 600 mph (800 to 970 kph). Supersonic transport planes can travel at 1,350 mph (2,180 kph).

Most airliners are powered by jet engines, which enable the planes to travel long distances at high speeds without refueling. Most four-engine jets, such as the Boeing 747, can fly nonstop 6,000 miles (9,700 kilometers) or more—farther than the distance between New York City and Tokyo, and can travel faster than 600 mph (970 kph). Four-engine jet transports fly at an altitude of 30,000 to 45,000 feet (9,100 to 13,700 meters), and so they stay above most storms.

Most three-engine jets are designed for shorter flights than four-engine jets. They can also use shorter runways. Some three-engine jetliners, such as the McDonnell Douglas DC-10, can carry as many passengers as most four-engine jets can carry.

Many twin-engine jetliners carry fewer passengers than three- or four-engine jets and are used for shorter trips to serve small and medium-sized cities. Other twin-engine jets fly long trips. The Boeing 777, for example, can carry more than 300 passengers over 7,200 miles (11,600 kilometers). Twin-engine, propeller-driven planes, such as the SAAB 2000, travel at less than 400 mph (640 kph) and make mostly short flights.

The Boeing Company

Cessna Aircraft Company

Passenger jets range in size from the enormous Boeing 747 jumbo jet, *above,* which can carry more than 400 people, to small business jets such as the Cessna Citation Bravo, *right,* which seats a maximum of 6 passengers. The 747 is the world's largest commercial airliner. Business executives use small jets like the Citation Bravo to fly to out-of-town assignments or meetings.

General aviation planes are smaller than most commercial transports and can thus land and take off at smaller airfields. Most of these planes are *light planes,* which generally weigh less than 2,000 pounds (900 kilograms) when empty and have two to six seats.

Most light planes are single-engine, propeller-driven planes owned by individuals. Many people fly such planes for personal transportation and enjoyment. Light planes have hundreds of other uses. For example, they are used to inspect pipelines and power lines, to spot and fight forest fires, and to deliver emergency aid. Some light planes are used to haul light cargo, to take pictures from the air, and to teach student pilots to fly. Farmers use light planes to help them plant seeds, check soil erosion, and count livestock.

The largest general aviation planes have two engines. Air taxi services and commuter airlines use such planes to transport passengers—usually fewer than 20—be-

McDonnell Douglas Corporation

A three-engine jet transport, such as the DC-10, *above,* generally makes shorter flights than four-engine jets do. But some carry nearly as many passengers as jumbo jets carry.

U.S. Air Force

Four-engine jet transports are designed for long nonstop flights. Commercial airlines own and operate most of these planes. But some, such as the Lockheed C-5A Galaxy, *above,* are military transports. The Galaxy is one of the world's largest airplanes. It carries battle tanks and other military equipment.

Raytheon Aircraft

Propeller-driven light planes are used to carry passengers and lightweight or perishable goods. They also perform many other tasks, from scattering seeds to carrying emergency aid.

U.S. Air Force

Military planes carry out special duties for a nation's armed forces. Jet fighters, such as the U.S. Air Force's F-16, *left,* are used chiefly to intercept and attack enemy aircraft.

Aerobatic planes perform difficult maneuvers, such as flying in close formation. These military jets are flown by the Blue Angels, the U.S. Navy's famous aerobatic team.

David R. Frazier Photolibrary

tween small airports and the large airports that serve larger airliners.

Many businesses own single- or twin-engine airplanes. Such *business planes,* also called *corporate planes,* are used to fly employees to out-of-town assignments or meetings.

Extremely light aircraft are flown for recreation. In the United States, where they are called *ultralights,* these one-seat, single-engine aircraft weigh no more than 254 pounds (115 kilograms) and carry only 5 gallons (19 liters) of fuel or less. Ultralights are allowed to fly only below 10,000 feet (3,000 meters) and at a speed of 63 mph (101 kph) or less. In other countries, these light aircraft are commonly called *microlights* and usually have two seats. They may weigh up to 496 pounds (225 kilograms) and carry up to 15 gallons (57 liters) of fuel. They are allowed to fly only below 10,000 feet and at a speed of 40 mph (65 kph) or less.

Military planes carry out a variety of duties for a nation's armed forces. Some military planes are special models of transports or light planes that the armed forces have bought from aircraft manufacturers. For example, the United States armed forces use special models of the Boeing 707 as tankers for refueling other planes in the air. Many other kinds of military planes are custom-made. Most are *bombers,* which mainly attack ground targets, or *fighters,* which mainly attack other aircraft. *Fighter-bombers* can both fight and drop bombs. One of the most advanced fighter-bombers is the Lockheed F-117A "stealth" fighter, a sleek plane designed to be nearly invisible to radar.

Some military planes are designed for tasks other than attacks on an enemy. For example, the Lockheed C-5A Galaxy is an enormous transport plane that can carry two battle tanks weighing 50 short tons (45 metric tons), or about 350 troops. Another Lockheed plane, the SR-71A, is designed to survey enemy forces and installations. It carries cameras and other equipment. The SR-71A flies as high as 100,000 feet (30,000 meters) and has a speed of more than 2,000 mph (3,200 kph), which makes it one of the fastest planes in the world. For more information on military planes, see Aircraft, Military; Air Force, United States (Planes and weapons of the Air Force).

Seaplanes can touch down and take off on water. There are three kinds of seaplanes: (1) floatplanes, (2) flying boats, and (3) amphibians. Floatplanes are equipped with big floats instead of wheels. Flying boats have a watertight body that floats in the water like the hull of a ship. Amphibians, which can land and take off on both land and water, are flying boats with retractable wheels attached to their floats or hull. The pilot raises the wheels when operating the plane on water and lowers the wheels on land.

Special-purpose planes. Many airplanes are built for particular jobs. For example, farmers use *agricultural spray planes* to spray their fields with liquid fertilizer or insecticide. These planes are built to fly slowly and to carry large tanks filled with chemicals. An amphibian plane made in Canada is designed for fighting forest fires. This plane can fly just above a lake and draw more than 1,000 gallons (3,800 liters) of water into its tanks. The

Ultralight planes, such as the one shown above, are flown for recreation. In the United States, ultralights weigh no more than 254 pounds (115 kilograms) and have one seat and one engine.

plane then flies to the fire and drops its load of water.

Special-purpose planes also include planes used for air races or *aerobatics* (air acrobatics). These are light planes that can perform difficult maneuvers. Another large category of special-purpose planes consists of *home-built* airplanes, which are built from plans or manufactured in kits for assembly by the owner.

Aircraft called *V/STOL*'s are designed to take off and land vertically or on a short runway. The term *V/STOL* stands for *V*ertical/*S*hort *T*ake-*O*ff and *L*anding. V/STOL's have great military value because they can land on small airfields near battlefields and on ships smaller than aircraft carriers. See V/STOL.

The parts of an airplane

All airplanes, except for a few experimental planes, have the same basic parts. They are (1) the wing, (2) the *fuselage* (pronounced *FYOO zuh lahzh*)—that is, the body of the plane, (3) the tail, (4) the landing gear, and (5) the engine. All these parts—except the engine—make up a plane's *airframe.*

This section of the article discusses the basic parts of the airframe, as well as airplane controls and instruments and types of propellers. The airplane engine is described in the next section. For information about how the parts of an airplane work to move the plane through the air and how a pilot uses airplane controls and instruments, see the section called *Principles of flight.*

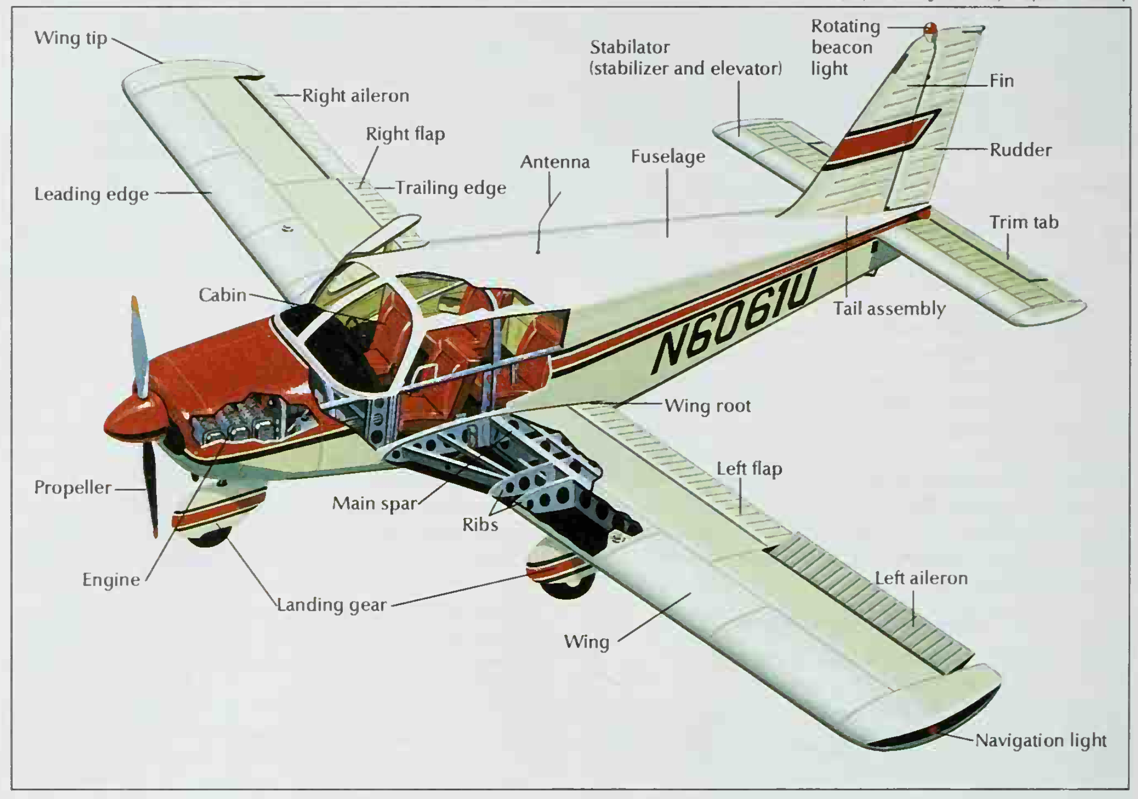
The wing. People usually think of an airplane as having two wings, but modern planes actually have only one. This wing is a single, continuous structure that extends outward from each side of the fuselage. A wing has a nearly flat bottom and a curved top. This shape helps create the lift that raises an airplane off the ground and keeps it in the air.

Most airplane wings are metal. They have a skeleton of lengthwise *spars* and crosswise *ribs.* The skeleton has a thin covering, usually of an aluminum *alloy* (mixture of metals). Most planes have a *cantilever* wing, which is completely supported by its internal structure.

An airplane wing has a *root, tip, leading edge,* and *trailing edge.* The root is the part of the wing attached to the fuselage. The tip is the edge of the wing farthest from the fuselage. The leading edge is the curved front edge of the wing. The top of the wing thickens from the leading edge and then slopes back to the knifelike trailing edge. On most airplanes, the wing tips are slightly higher than the wing roots. Such wings are called *dihedral* wings. Many planes have a *low-wing* design—that is, the wing is joined to the lower part of the fuselage. In planes of *mid-wing* design, the wing is attached about halfway up the side of the fuselage. *High-wing* planes have the wing near the top. In planes of *straight-wing* design, the wing's leading edge and the fuselage form a right angle. Most planes have this design because it performs well at both high and low speeds.

Many high-speed airplanes, especially jets, have a *sweptwing.* Such a wing, also called a *swept-back wing,* slants backward from the root to the tip. A few planes have a wing that is *swept forward.* A *delta wing* is shaped like a triangle. The root may be almost as long as the fuselage, and the leading edge is deeply swept-back. This design provides for both high speed and great lift.

Most airplane wings have movable control surfaces that help balance the plane in flight. The *ailerons* are hinged sections along the trailing edge of the wing. They can be moved up or down to control the plane's *lateral stability* (balance from side to side). The ailerons are used to make the plane *bank* (tilt) to the right or to the left for a turn. When one aileron is raised, the other is lowered. On most planes, each aileron has a small



McDonnell Douglas Corporation

V/STOL's, or *V*ertical/*S*hort *T*ake-*O*ff and *L*anding planes, can take off and land without runways or on short ones. These planes can land easily on ships and can also use small airfields in large cities or in rural areas, *left.*

The parts of an airplane This drawing shows the parts of a light plane, a Piper Cherokee. The basic parts are the wing, *fuselage* (body), tail, landing gear, and engine. Some other parts, such as the ribs and spars in the wing, are structural. Still other parts, including the ailerons, flaps, rudder, and stabilator, are used to control the plane. The drawing also shows the wing's root, tip, and leading and trailing edges.

WORLD BOOK illustration by Tom Morgan, courtesy of Piper Aircraft Corp.

hinged section called a *trim tab.* A pilot uses the trim tabs to regulate the pressure that must be applied to other controls in keeping the plane in *trim* (balance) in flight. There are usually trim tabs on the movable parts of the tail as well as on the ailerons.

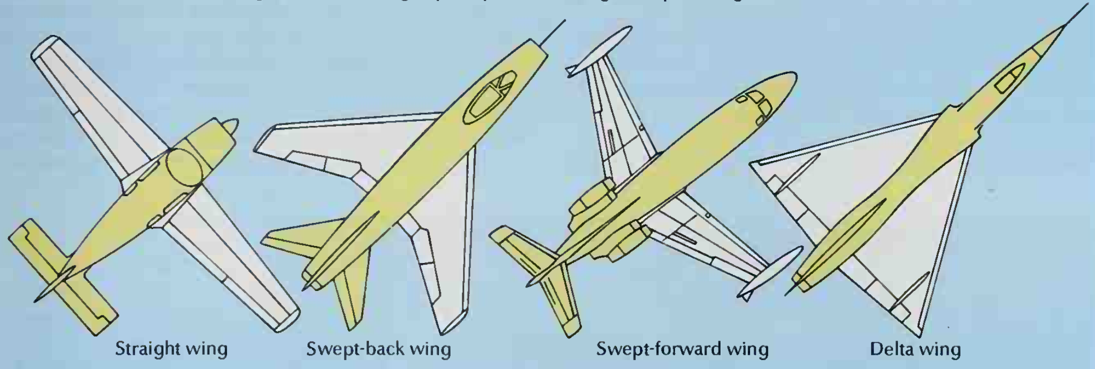
Many airplanes have *flaps.* These hinged sections along the trailing edge of the wing are near the root. The flaps are lowered to help increase the plane's lift during take-off and to increase the plane's drag during landing.

Some planes have additional wing controls. A *spoiler* is a plate on the upper part of each side of the wing. A pilot can raise both spoilers to act as air brakes. If the pilot raises the spoiler on one side only, it makes the plane bank in that direction. Some airplanes have spoilers instead of ailerons. A *slat* is a hinged section on the leading edge of the wing. At low speeds, the slats automatically slant forward and help the wing provide extra lift. A *slot* is an opening behind the leading edge near each wing tip. Slots also help produce more lift at low speeds.

Many airplanes have their engines on or in the wing. The engines are enclosed in metal casings called *nacelles (nuh SEHLZ).* Most wings also have space inside for fuel tanks and landing gear. Various lights are also located on the plane's wing. For example, each wing tip has a colored *navigation light,* also called a *position light.* The light on the plane's left wing tip is red, and the light on the right wing tip is green. By noting the position of these two lights, a person can tell the direction in which a plane is traveling.

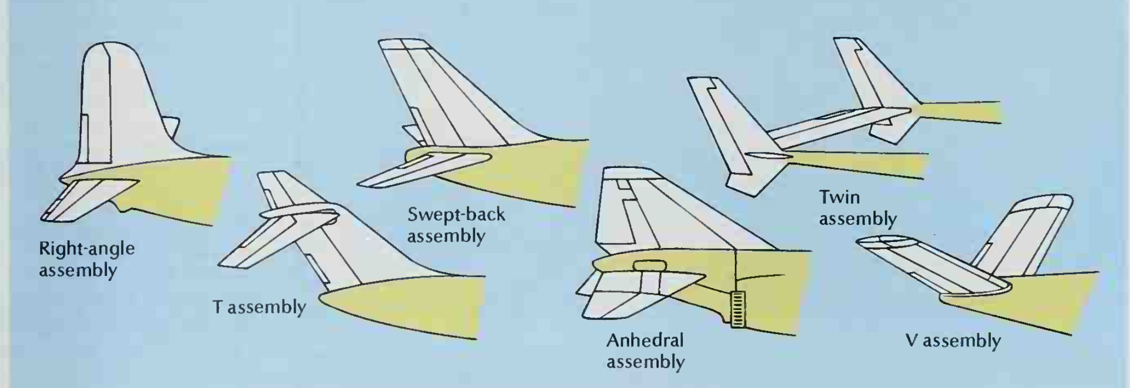
The fuselage of an airplane extends from the nose to the tail. Most airplane bodies have a tubelike shape and are covered with a lightweight aluminum skin. The name *fuselage* comes from the French word *fuselé,* which means *spindle-shaped.* The engine of most single-engine planes is in the front part of the fuselage. However, some multiengine jet planes have their engines at the rear of the fuselage.

The fuselage houses the controls, crew, passengers, and cargo. In the smallest airplanes, the fuselage contains a cockpit with room for only the pilot, or for the pilot and one passenger. In most planes that carry from two to six people, the pilot and passengers sit together in a single cabin. Most large planes have a cockpit for the crew and a cabin for the passengers and cargo. In enormous planes, such as the Boeing 747 and the McDonnell Douglas MD-11, the cabin has separate *decks* (floors) for the passengers and cargo.



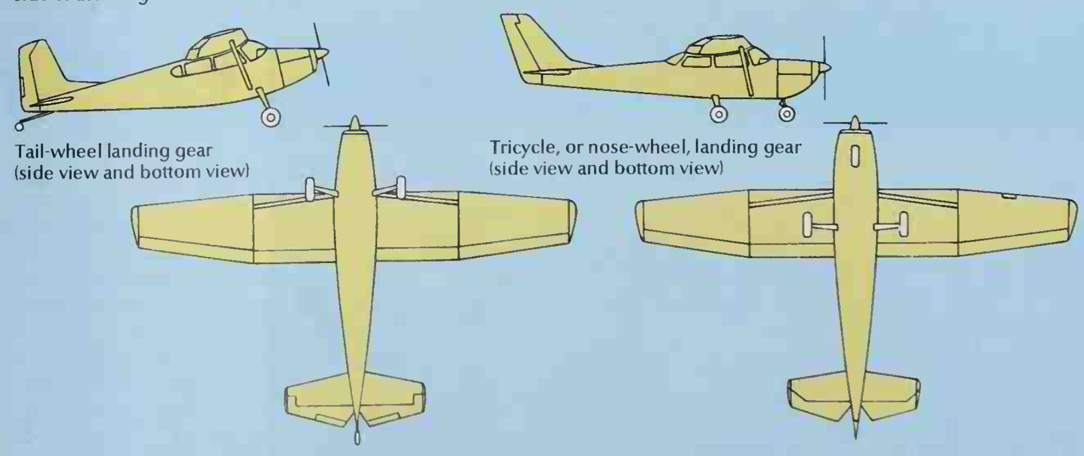
The tail, also called the *empennage (ehm PEHN ahj),* is the rear part of an airplane. It helps guide the plane and keep it balanced in flight, much as feathers do on an arrow. Most tails consist of a vertical *fin* and *rudder* and a horizontal *stabilizer* and *elevator.* The fin stands upright and does not move. It keeps the rear of the plane from swinging to the left or right. The rudder is hinged to the

Text continued on page 216.



Wing, tail, and landing gear designs

WORLD BOOK diagrams



Wings have various shapes, depending on the planes for which they are designed. *Straight wings* perform the best at both high and low speeds. *Sweptwings* (also called *swept-back wings*), *swept-forward wings,* and *delta wings* are used on high-speed jets. Delta wings also provide great lift.

Tails. The fin and rudder, which make up the vertical surfaces of the tail, may be at a right angle to the fuselage or swept-back. Some planes have twin or triple fins. The stabilizer and elevator, the horizontal surfaces of the tail, are near the top of the vertical surfaces in a T-tail and attached to the fuselage in an anhedral tail. A V-tail has two fins in a V shape, each with an elevator and trim tab.

Landing gears. Some planes have a *tail-wheel landing gear*—1 wheel under the tail and 1 under each side of the fuselage or wing. Most planes have a *tricycle landing gear*—1 to 4 wheels under the nose and 2 to 20 under the midfuselage or 1 or 4 wheels under the nose and 1 to 10 under each side of the wing.

rear edge of the fin and can be moved from side to side. It helps control the plane during a turn.

The stabilizer is like a small wing in the tail. It prevents the tail from bobbing up and down and so keeps the plane flying at a steady altitude. The elevator is hinged to the rear edge of the stabilizer. A pilot moves the elevator up or down to raise or lower the plane's nose.

Many modern airplanes have a *stabilator* instead of a stabilizer and an elevator. A stabilator is a single solid unit that moves up or down. Almost all planes have a trim tab on the elevator or stabilator, and some have a trim tab on the rudder.

Tails have various shapes and arrangements. On some planes, the fin and rudder stand upright at a right angle to the fuselage. On other planes, they slant back at a sharp angle. Most jet planes with engines at the rear of the fuselage have their horizontal stabilizer and elevator mounted across or near the top of a tall vertical fin and rudder. Some light airplanes have a V-tail. This type of tail consists of two fins in a V-shape with an elevator and a trim tab attached to each fin.

The landing gear, also called the *undercarriage,* consists of the wheels or floats upon which an airplane moves on the ground or water. The landing gear also supports the weight of a plane on the ground or water.

Landplanes have two main types of landing gear. In

Raytheon Aircraft

The Boeing Company

Instrument panels range from a relatively compact panel in the cockpit of a single-engine plane, *left,* to a vast array of dials, switches, and electronic displays that extend over the front, ceiling, and side walls of the flight deck of a Boeing 747 jumbo jet, *below left.*

some light planes, landing gear consists of a wheel under each side of the wing or front part of the fuselage and a third wheel under the tail. Most airplanes, however, have a *tricycle landing gear.* On light planes, it consists of a wheel under the nose and two wheels under the midfuselage or one under each side of the wing. Many large airplanes have a tricycle landing gear made up of (1) a *main gear* with from 1 to 10 wheels under each side of the wing or from 2 to 20 wheels under the midfuselage and (2) a *nose gear* with 2 or 4 wheels.

Landing gear may be fixed or retractable. Fixed landing gear remains extended in flight. The extended gear increases air resistance and thus slows down the plane. Retractable landing gear can be *retracted* (drawn back) into either the wing or the fuselage after take-off. Most high-speed planes use retractable landing gear.

The watertight body of a flying boat serves as both landing gear and cabin. Floats serve as the landing gear for floatplanes. Amphibians, which operate from land or water, have retractable wheels in their floats or hull.

The controls and instruments. Inside the cockpit, the pilot has a variety of controls, instruments, and navigation aids. Most planes have a *yoke* (control wheel) that operates the ailerons and elevator. A few special types of planes, such as fighters and spray planes, have a control *stick* instead of a yoke. Two *rudder pedals* on the floor control the rudder. Various engine instruments display information on the fuel supply, oil pressure, and other conditions affecting the engine. Flight instruments show the plane's speed, altitude, and *attitude* (position in relation to the horizon).

Some airplanes have an automatic pilot, also called an *autopilot.* This device is connected to the airplane's controls and automatically keeps the plane on course.

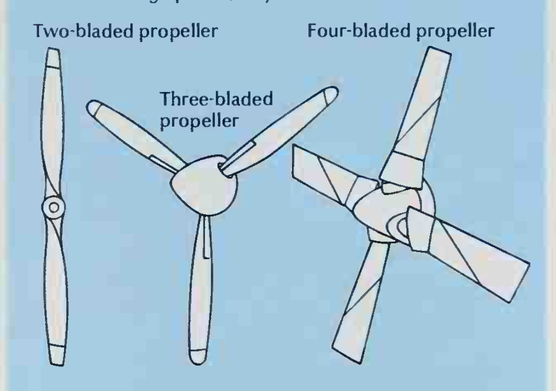
Propellers, also called *airscrews,* move turboprop planes and planes with reciprocating engines through the air. On most such planes, each propeller has its own engine. However, a few planes have *coaxial propellers*—two propellers turned by a single engine. On most single-engine planes, the engine and a single propeller are mounted at the front of the fuselage. Most propeller-driven planes with more than one engine have their engines and propellers on the wing.

Small planes have a two- or three-bladed propeller. Larger planes have propellers with up to six blades. Many planes have *controllable-pitch propellers.* A pilot can change the angle of the blades on these propellers in flight. A particular blade angle is best suited to a particular speed or maneuver. With the blades at the proper angle, the plane operates most efficiently. On *fixed-pitch propellers,* the angle of the blades cannot be changed. *Constant-speed propellers* adjust their blade angle automatically and so keep the plane's engine speed steady during any maneuver.

The blades of *feathering propellers* can be turned to a right angle so that their edges are parallel to the plane's flight path. If a plane's engine is disabled, a pilot angles a feathering propeller to decrease air resistance. This action also keeps the wind from spinning the propeller and so prevents possible damage to the engine.

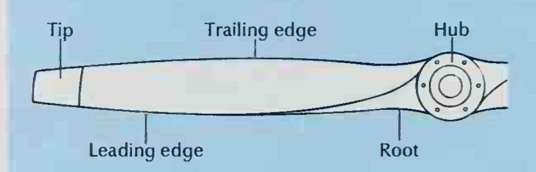
Power for flight

An airplane's engine produces the power that makes the plane move fast enough to fly. Airplanes use three main types of engines: (1) reciprocating engines, (2) jet engines, and (3) rocket engines. Reciprocating engines are the heaviest and least powerful of these engines, and rocket engines are the most powerful. Most small airplanes and many large ones have reciprocating engines. Nearly all newer airliners and some private planes have jet engines. Rocket engines are used mainly for research.



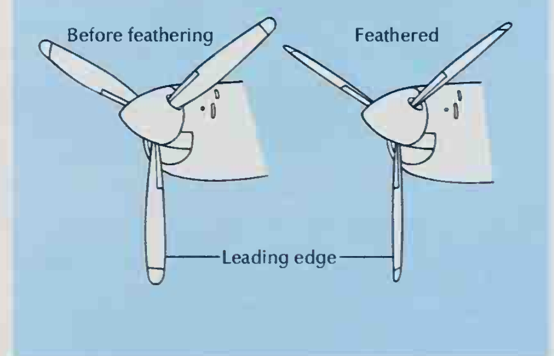
Reciprocating engines, also called *piston engines,* are the most widely used type of airplane engine. Airplanes that use reciprocating engines also have one or more propellers. The engine turns the propeller, which moves the plane through the air.

Text continued on page 220



Airplane propellers

WORLD BOOK diagrams; courtesy of Hartzell Propeller, Inc.



Propeller designs vary according to the type of plane. On most light planes, propellers have two or three blades. On large planes, they have three to six blades.

A propeller blade resembles a plane wing. Like a wing, it has a tip, root, leading edge, and trailing edge. The blades are attached to an engine-driven shaft by a *hub.*

A feathering propeller has blades that can be turned on edge if the engine fails. This action reduces air resistance and stops the propeller from spinning.

Parts of a passenger jet airplane

A large jet airliner can fly hundreds of passengers long distances. This drawing shows the features of a Boeing 777-200, one of the largest twin-engine jetliners.

WORLD BOOK illustrations by Kim Downing

The tail

The tail helps guide the plane and keeps it balanced in flight. The *fin* keeps the rear of the plane from swinging to the left or right. The *rudder* helps control the plane during a turn. The *stabilizers* prevent the tail from bobbing up and down.

Wing control surfaces

Each side of a jetliner's wing has movable surfaces that help control the plane in flight. The *ailerons* are used to make the plane *bank* (tip) to the right or left for a turn. The *flaps* can be lowered to increase the plane's lift during take-off or its drag during landing. The pilot can raise the *spoilers* to act as air brakes.

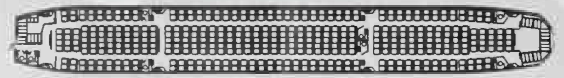
Baggage

Baggage handlers pile suitcases and other checked luggage into large luggage containers, which are then loaded into the cargo hold of the aircraft. The 777-200 carries 32 luggage containers that hold more than 5,000 cubic feet (140 cubic meters) of baggage.

Luggage container

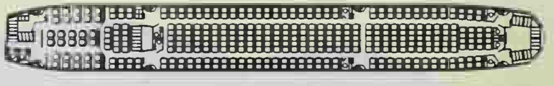
Facts in brief about the Boeing 777-200



Length: 209 ft. 1 in. (63.7 m)
Wingspan: 199 ft. 11 in. (60.9 m)
Maximum weight at take-off: 632,500 lb. (286,900 kg)
Range: 7,230 nautical mi. (13,390 km)
Cruising speed: 550 mph (890 kph)

Flexible seating

Seating arrangements vary among airlines. A 777-200 may carry up to 440 passengers. But the maximum number varies depending on the seating plan. These diagrams show three common seating plans.



The Boeing Company

One class

418 passengers

Two classes

30 first class 345 economy class
375 passengers

Three classes

24 first class 54 business class 227 economy class
305 passengers

Fuel tanks
A jetliner's main fuel tanks are inside the right and left wing and in the center section of the plane. The 777-200's tanks hold 31,000 gallons (117,000 liters) of aviation fuel.

Engines
Most jetliners have *turbofan* engines, jet engines with a propellerlike fan at the front that draws in huge amounts of air. The 777-200 has two large turbofan engines that produce up to 84,000 pounds (374,000 newtons) of thrust each.

Flight deck
Instrument panels in the flight deck display information that helps the pilot and copilot keep the airplane on course and monitor the operation of the engines. The 777-200 has six large display screens that provide navigation information and engine data.

Landing gear
Most jetliners have *retractable* landing gear, which tucks away during flight. The 777-200's main landing gear is under the wing and not shown here. It has 12 wheels.

Meals in the air
Airline catering companies prepare and refrigerate hundreds of meals and load them onto the plane at the airport. At mealtime, flight attendants reheat the food in microwave ovens in the galleys.

Other large jetliners

The twin-engine Boeing 777-200 is slightly larger than two other wide-bodied jets that serve similar markets, the four-engine Airbus A340-200 and three-engine McDonnell Douglas MD-11.

A reciprocating engine in an airplane works much like one in an automobile. Both burn a mixture of gasoline and air inside cylinders. The burning fuel-air mixture forms a fine spray, which explodes. The explosion drives pistons inside the cylinders up and down. This pumping motion rotates a crankshaft. In an airplane, the rotating crankshaft turns the propeller. In an automobile, the crankshaft turns other parts of the car that make the wheels spin.

Reciprocating engines in airplanes differ from those in automobiles in some ways. In most airplane engines, for example, the cylinders are arranged in a circle or opposite each other. In automobile engines, they are arranged in a single line or a V-shape. In addition, most airplane engines are cooled by air, but most automobile cooling systems use a mixture of water and antifreeze.

The power of reciprocating engines is measured in units of horsepower or kilowatts. Most reciprocating engines made for airplanes range from 65 horsepower (50 kilowatts) for small single-engine planes to about 400 horsepower (300 kilowatts) for larger two-engine planes. The most powerful reciprocating engines ever used on an airplane were the 3,650-horsepower (2,722-kilowatt) engines of the huge B-36 bomber of the late 1940's. Large, high-speed airplanes no longer use such powerful reciprocating engines. These airplanes are powered by jet engines, which weigh less than reciprocating engines but produce much greater power. Reciprocating engines are still used for most light airplanes because they work better than jet engines at low speeds.

Jet engines enable large airplanes to travel long distances at high speeds. But to be useful in an airplane, a jet engine must also operate well at low speeds for safe take-off and landing. Airplanes use three main types of jet engines. They are (1) *turbojets;* (2) *turbofans,* also called *fanjets;* and (3) *turboprops.*

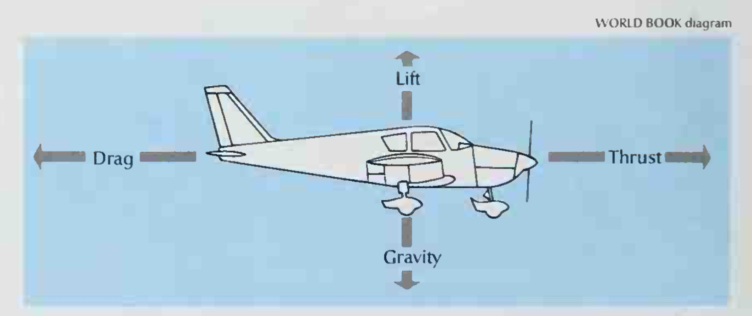
The turbojet was the first successful jet engine and is still used on some airplanes. Like other jet engines, the turbojet takes air in through the front and burns it with fuel. This process forms a powerful jet exhaust. The exhaust moves backward through the engine at tremendous speed, which causes the engine to move forward at an equally high speed. Before the jet exhaust passes out the engine's tail pipe, it spins a device called a *turbine,* which consists of a set of blades attached to a shaft. The turbine runs the various parts of the engine. See **Jet propulsion** (How jet propulsion works).

Almost all new airliners have turbofan engines, which are an improvement on the turbojet. A turbofan works much like a turbojet, but it has a fan at the front that draws in huge amounts of air. Only part of the air is burned with the fuel to form the jet exhaust. The rest is added to the exhaust as it passes out the tail pipe. The resulting exhaust is much more powerful and much cooler than that of a turbojet. In addition, turbofans use less fuel than turbojets do, make much less noise, and operate better at low speeds.

Turboprop planes use turbojet engines to turn propellers. The name is a combination of the words *turbojet* and *propeller.* Turboprop planes combine the tremendous power of the jet engine with the propeller's useful ability to fly at low speed.

Rocket engines work much like jet engines, except that they do not need a supply of oxygen from outside the engine. A rocket engine operates best at extremely high speeds. It also burns much fuel, and so it is expensive to operate. In addition, the possibility of explosion makes rocket engines too dangerous to power passenger airplanes. But a few jet and turboprop military planes use small rockets to help them take off quickly with heavy loads or on short runways. The rockets are attached to the plane's body or under its wing. This system is called *R*ocket-*A*ssisted *T*ake-*O*ff (RATO). Rocket engines have powered many supersonic test planes, such as the Bell X-1 and North American X-15. See **Rocket.**

Principles of flight

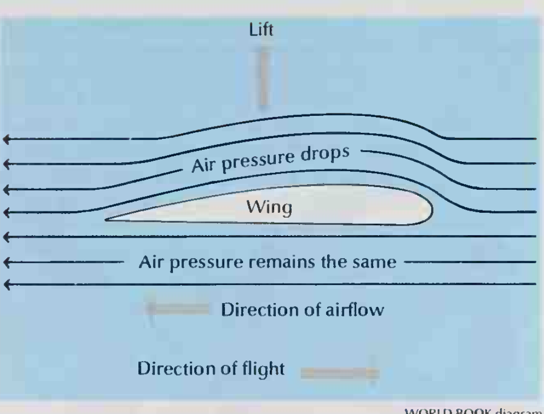


Four basic forces govern the flight of an airplane: (1) gravity, (2) lift, (3) drag, and (4) thrust. Gravity is the natural force that pulls a plane toward the ground. Lift is the force that pushes a plane upward against the force of gravity. It is created by the plane's wing as it moves through the air. Drag is the natural force of air that resists an airplane's forward movement. Thrust is the force that moves a plane forward. Thrust is created by a plane's propeller or by its jet engines.

Gravity and lift are opposing forces, as are drag and thrust. When a plane's lift equals the force of gravity and its thrust equals the drag, the plane is in level, cruising flight. When one or more of the four forces change, the plane begins to change its altitude, direction, or speed.

Gravity and lift. Gravity tends to keep an airplane on the ground or to pull it to the earth when in flight. The force of gravity on the ground equals the weight of the plane on the ground. For a plane to become airborne and to stay in the air, its wing must create a lifting force greater than the downward force of gravity.

Lift is created by a change of air pressure around an airplane's wing as the plane moves. When a plane stands on the ground, the air pressure above and below its wing is the same. As the plane starts to move forward, air begins to flow over and under the wing. The air mov-

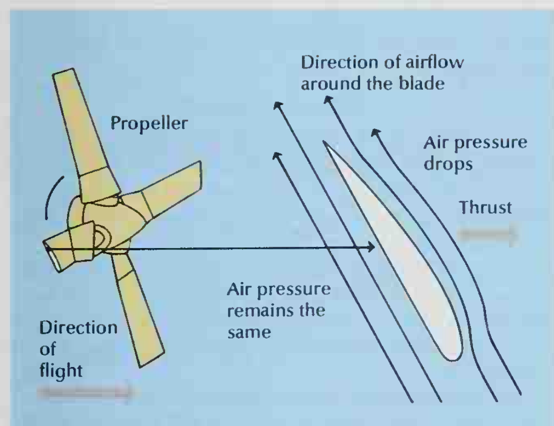


WORLD BOOK diagram

Four forces act on an airplane in flight: (1) gravity, (2) lift, (3) drag, and (4) thrust. Gravity is the natural force that pulls a plane toward the ground. Lift opposes gravity and pushes the plane upward. Drag is the natural force of air opposing a plane's forward movement. Thrust opposes drag and moves the plane forward.

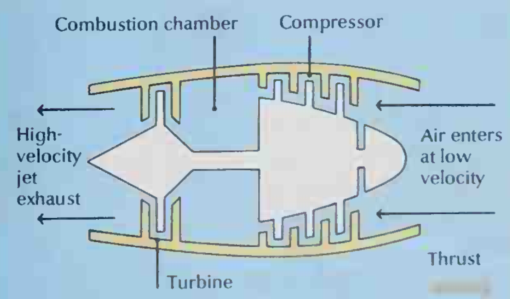
ing over the curved upper surface must flow in a curve and, as a result, must travel farther. Because this air travels farther, its speed increases and its pressure drops. The air moving under the flat bottom of the wing moves in a straight line. Its speed and pressure are not changed by the wing. Because air in a high-pressure area always moves toward a low-pressure area, the air under the wing tries to move upward to the air over the wing. It is unable to do so, however, because the wing is in the way. Instead of meeting the low-pressure area, the air creates a pushing force that lifts the wing upward.

The faster the airplane moves, the greater the lift its wing produces. As an airplane increases its speed down the runway before take-off, its wing builds up more and more lift. The air pressure beneath the wing finally becomes greater than the weight of the plane, and so the force of the lift becomes greater than the force of gravity. The plane then takes off.



WORLD BOOK diagram

Lift is created by a drop in air pressure over a plane's wing. The wing has a curved upper surface. As the plane moves forward, the pressure of the air that rushes over this curved surface falls. Air in a high-pressure area always moves toward a low-pressure area. The air in the high-pressure area below the wing thus rises toward the low-pressure area above it and lifts the airplane.



How thrust is produced

Propellers produce thrust in gasoline-powered and turboprop airplanes. Jet engines produce thrust in jet planes.

WORLD BOOK diagrams

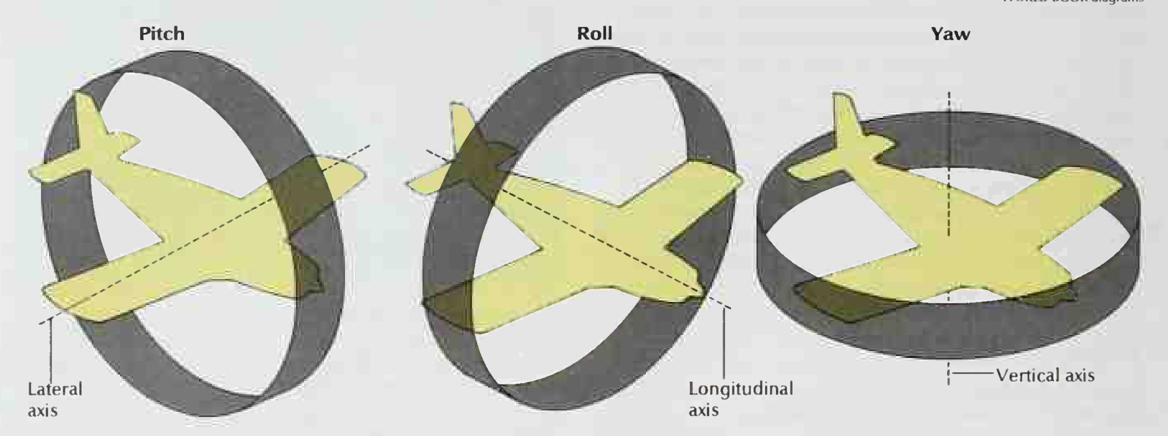
Propeller blades have a front surface curved like the upper surface of an airplane wing. As the propeller spins, the air pressure in front of the blades drops. The air in the high-pressure area behind the blades moves toward the low-pressure area in front and so produces thrust. The faster the propeller spins, the greater the thrust.

A jet engine takes in air at low *velocity* (speed). A *compressor* increases the pressure of the air. The compressed air is then burned with jet fuel in a *combustion chamber,* forming a high-velocity exhaust. The exhaust moves rapidly backward through the engine, which causes the engine to move forward. The exhaust also spins a *turbine,* which runs the engine parts.

Drag and thrust. A wing can produce lift only if it is moving forward through the air. A plane needs thrust to create the required forward movement.

In a jet airplane, the rapid movement of gases through the jet engine produces thrust. Propellers produce thrust in turboprop planes and planes powered by reciprocating engines. Propeller blades are shaped much like airplane wings. As the propeller spins, the air pressure on the front surface of the blades is reduced. The higher pressure air on the back of the blades pushes toward the lower pressure area on the front, moving the plane forward. The faster the jet engine works or the propeller spins, the greater the force of thrust.

To reduce drag, engineers design airplane bodies to be as streamlined as possible. They make the bodies sleek and trim, and they design every part on the outside of the aircraft so that it will slip through the air easily and smoothly.



Changing altitude. An airplane cruising in level flight has lift balanced against gravity and thrust balanced against drag. To enable the airplane to descend, the pilot must decrease engine power. The propeller or engines slow down, reducing the plane's thrust. The reduction in thrust also reduces lift, and the airplane begins to descend. At the same time, drag increases its effect, which further slows the airplane and thus adds to the rate at which the plane descends.

To climb, the pilot increases the engine power, creating more thrust. As a result, the plane moves faster through the air. The faster speed increases lift, and the airplane begins to climb. However, climbing adds more drag, and so the plane needs still more lift. To get additional lift, the pilot increases the airplane's *angle of attack*—that is, the angle at which the wing cuts through the air. The pilot uses the controls to make the aircraft's nose point up slightly so that the wing is at an upward angle to the path of the plane's flight. The flow of air over the upper part of the wing gains speed and produces added lift.

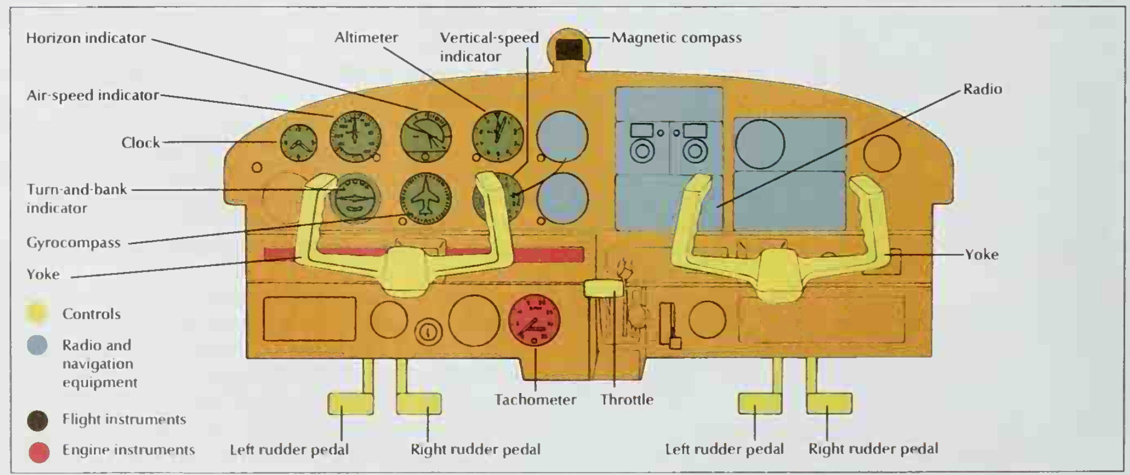
An airplane's basic movements

An airplane has three basic movements: (1) *pitch,* (2) *roll,* and (3) *yaw.* The airplane makes each movement on an imaginary axis. Pitch is the plane's movement on its *lateral axis* as the nose moves up or down. Roll is the plane's movement on its *longitudinal axis* as one wing tip dips lower than the other. Yaw is the plane's movement on its *vertical axis* as the nose turns left or right.

WORLD BOOK diagrams

Changing direction. A pilot turns a plane by *banking* (tilting) the wing left or right. Lift always occurs at a right angle to the surface of the wing. It is the lifting force of the wing, occurring at an angle to the horizon, that makes the airplane turn. The rudder is not used to turn the plane but only to balance the turn.

When a plane makes a turn, the amount of lift opposing the force of gravity is reduced. Unless the pilot brings lift and gravity back into balance, the plane begins to lose altitude. To produce greater lift, the pilot raises the nose slightly to increase the angle of attack. In making a steep turn, a pilot increases the angle of attack and the engine power at the same time to keep the plane from losing altitude.



For more information on how an airplane flies and on how basic forces of gravity, lift, drag, and thrust act on a plane in flight, see the *World Book* article on **Aerodynamics.**

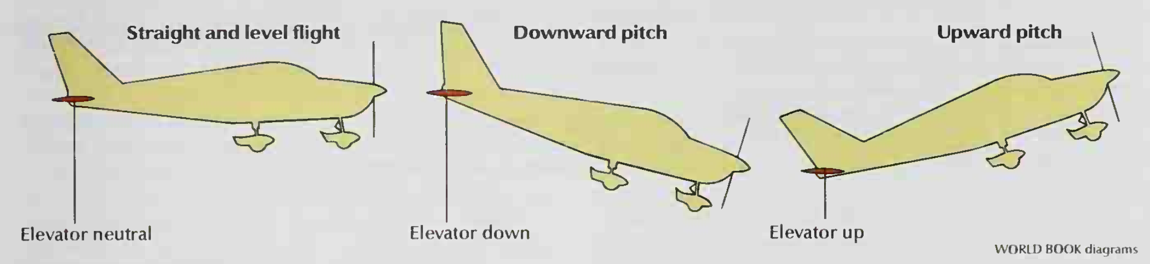
Flying an airplane

An airplane is a mechanical device that obeys mechanical laws. To become a skilled airplane pilot, a person must understand these laws and the laws of aerodynamics. The person must also have training and experience in flying an airplane.

Flying an airplane differs from driving an automobile in many ways. To make a turn in an automobile, for example, the driver simply turns the steering wheel. But to make a turn in an airplane, the pilot must operate several controls at once.

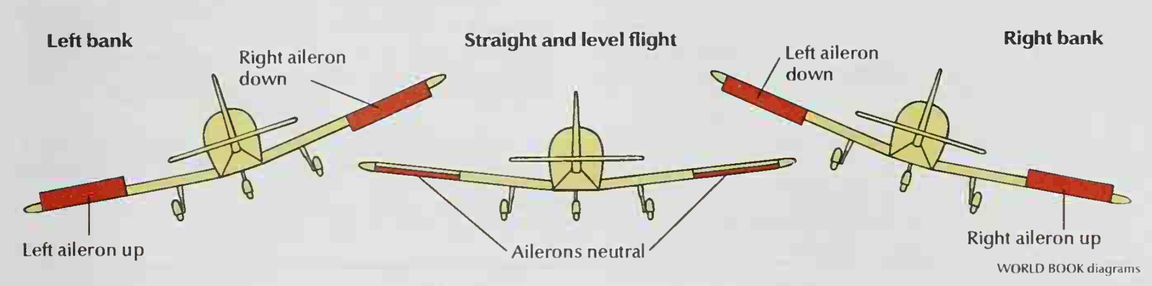
Basic movements and controls. An airplane has three basic movements: (1) *pitch,* (2) *roll,* and (3) *yaw.*

WORLD BOOK diagram, courtesy Piper Aircraft Corp.



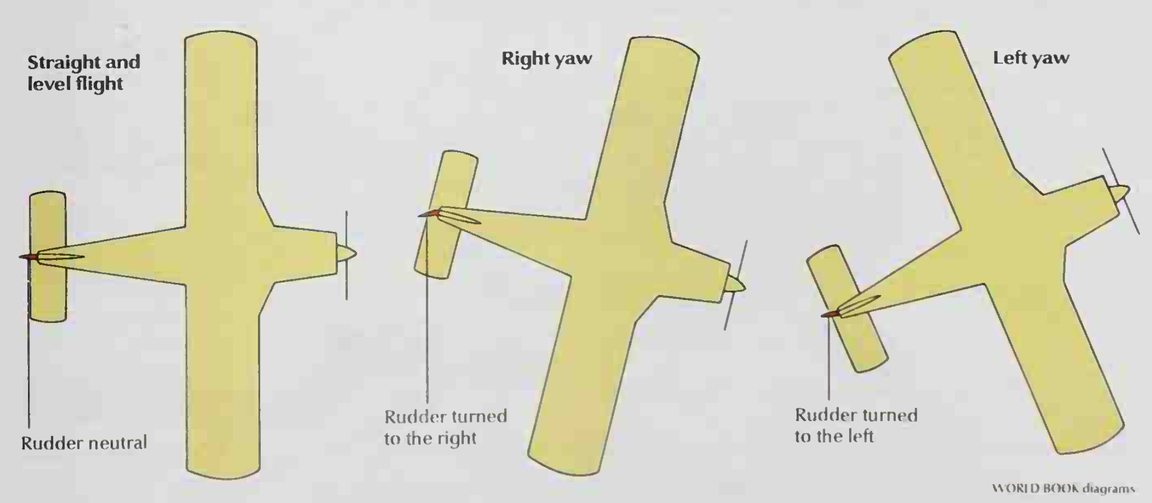
Basic cockpit controls and instruments. Both the pilot's and copilot's yokes control the ailerons and elevator. Their pedals operate the rudder. The throttle controls engine power and speed. *Flight instruments,* such as the air-speed indicator and altimeter, help keep the plane on course. *Engine instruments,* such as the oil-pressure gauge and tachometer, measure engine operations.

Pitch is the motion of a plane as its nose moves up or down. A plane rolls when it banks—that is, when one wing tip dips lower than the other. Yaw is a plane's motion as the nose moves left or right. A pilot uses the controls to make these movements and to adjust for them.



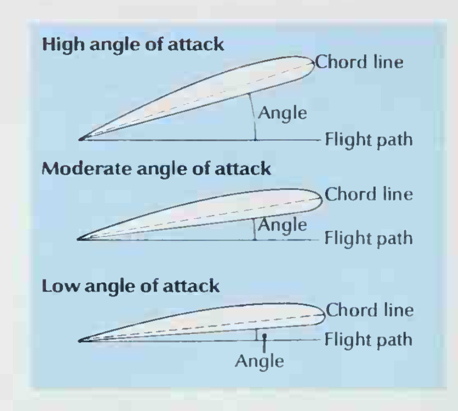
An airplane has many controls, but four of them are basic. They are (1) the elevator, (2) the rudder, (3) the ailerons, and (4) the throttle. The elevator and rudder are parts of the tail assembly. The ailerons are on each side of the wing. A system of cables, rods, and pulleys leads from these outside flight controls to the pilot's controls in the cockpit. The pilot's yoke or stick controls the ailerons and elevator. The rudder pedals control the rudder. The pilot uses the throttle to control the engine speed and power.

The yoke and rudder pedals make the plane pitch, roll, or yaw. The yoke moves forward and backward and turns from side to side. Pushing the yoke forward or pulling it backward moves the elevator up or down and makes the plane pitch up or down. When the yoke is pushed forward, the elevator lowers and the nose drops. When the yoke is pulled back, the elevator moves up, forcing the nose up. Turning the yoke from side to side raises or lowers the ailerons and makes the plane roll. When the yoke is turned to the right, the right-wing aileron goes up and the left-wing aileron goes down. The plane then rolls to the right. Turning the yoke to the left makes the plane roll to the left. The pilot operates the two rudder pedals to make the plane yaw. Pushing on the left pedal swings the rudder to the left, causing

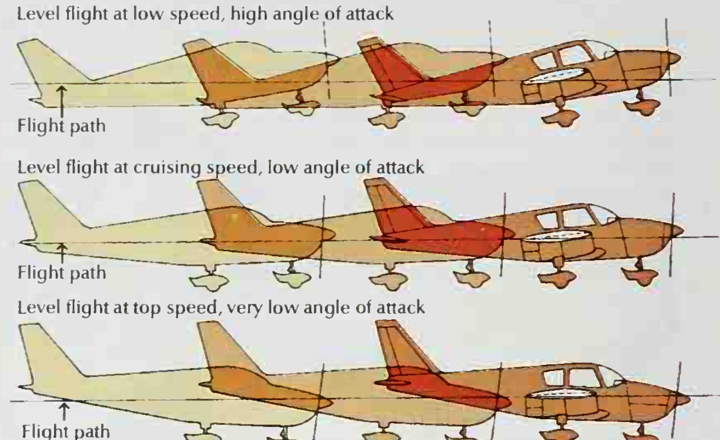


Text continued on page 225.

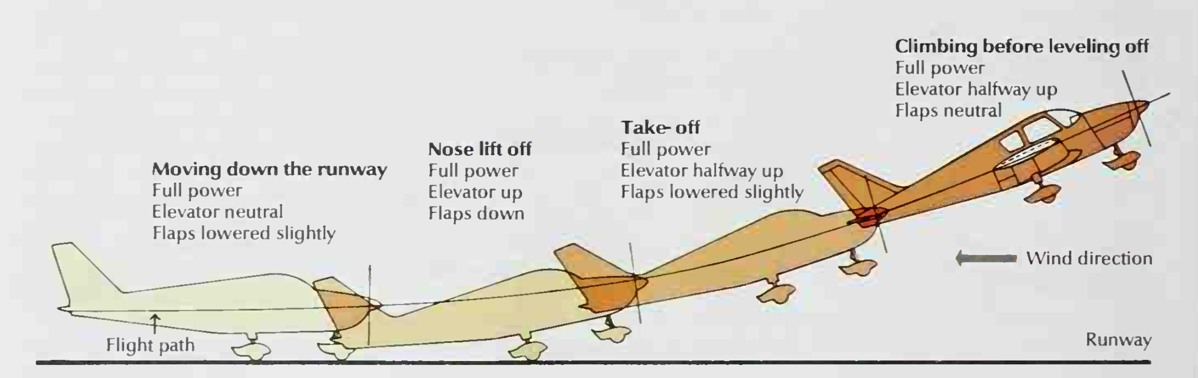
To make a plane pitch, the pilot lowers or raises the elevator. The pilot lowers the elevator by pushing the yoke forward and raises it by pulling the yoke back.



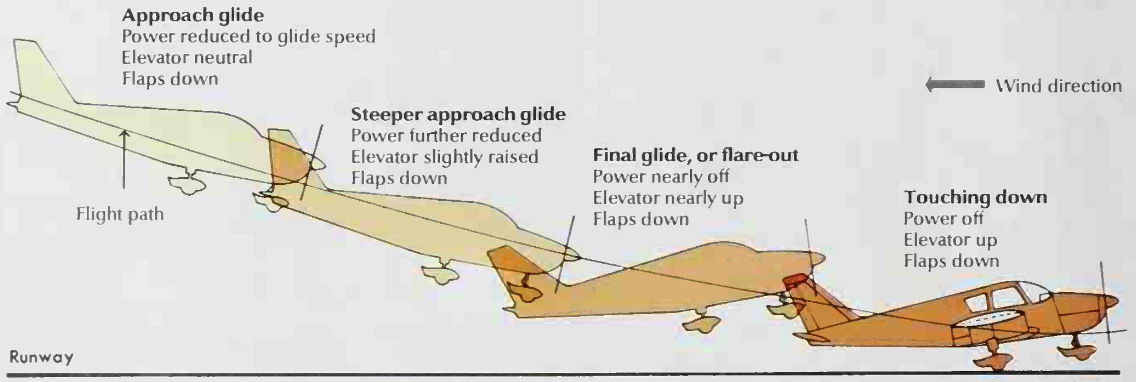
To make a plane roll, or *bank,* the pilot operates the ailerons. To make a left bank, for example, the pilot turns the yoke to the left, which raises the left aileron and lowers the right one.



To make a plane yaw, the pilot operates the two pedals that control the rudder. The pilot presses the right pedal to swing the rudder to the right and the left pedal to swing it to the left.



How a pilot uses angle of attack



Angle of attack is the angle formed by a plane's flight path and an imaginary *chord line* through the wing. A pilot raises the elevator to increase the angle of attack. In so doing, the pilot gives the plane added lift. But if the angle becomes too great, lift decreases dangerously.

For level flight, a plane must keep lift balanced against gravity. If its speed is reduced, the plane loses lift. To regain lift, the pilot increases the angle of attack. As speed increases, the angle of attack can be reduced.

For take-off, a plane moves down the runway at high speed. The wind rushes around the wing, building up lift. To get more lift, the pilot raises the elevator, increasing the angle of attack. The pilot may also lower the flaps. When lift becomes greater than gravity, the plane takes off.

WORLD BOOK diagrams

For landing, a plane's speed must be reduced as much as possible, and so the pilot decreases the engine power. But reducing speed also reduces lift. The plane must recover enough lift to counteract gravity. To recover lift, the pilot increases the angle of attack and lowers the flaps.

the plane's nose to swing left also. Pushing on the right pedal swings the rudder and nose to the right.

The pilot also has cockpit controls for the trim tabs on the ailerons, elevator, and rudder. The trim tabs help keep a plane balanced in spite of changes in the plane's air speed or its center of gravity. A plane's center of gravity changes many times in flight. For example, the center of gravity changes as the fuel in the plane's tanks is used. To keep the plane from pitching up or down because its center of gravity is changing, the pilot would have to keep constant pressure on the yoke. But if the pilot adjusts the elevator trim tabs, they adjust the elevator to handle the change in the center of gravity and thus help keep the plane balanced.

Proper use of the controls. To make any maneuver, an airplane pilot never uses only one basic control. To make a left turn, for example, a pilot does not simply press down on the left rudder pedal. Using only this one control would send the airplane into a left *skid.* An airplane in a skid does not complete its turn. It returns to its original course of flight as soon as the pilot releases the rudder pedal.

To make a left turn in level flight, a pilot must (1) turn the yoke to the left to raise the left aileron and lower the right aileron for a left bank; (2) press down on the left rudder pedal to make the plane's nose swing to the left; and (3) pull back on the yoke to bring up the elevator and raise the nose, which increases the wing's angle of attack. In a steep turn, the pilot might also need to push the throttle forward to increase engine power. The pilot makes all these movements at the same time, but they soon become second nature for an experienced pilot.

For all other airplane maneuvers—from taking off to landing—a pilot must also keep all the forces of flight in balance, just as in making a turn. By using all the basic controls at once, a pilot balances lift against gravity and thrust against drag.

Stalling occurs when the wing's angle of attack becomes so great that the plane loses lift and begins to fall. If a pilot brings the plane's nose up so that the wing is at an angle of more than 15 to 20 degrees to the flight path, the air flowing over the wing will bubble wildly. As a result, the plane stalls. The pilot can bring the plane out of the stall by lowering the nose and letting gravity build up the speed needed for lift. The pilot can also increase engine power to regain flying speed.

Flying by instruments. A pilot can maneuver a plane without being able to see anything but the plane's instruments. This skill is necessary when flying in clouds, fog, or heavy rain. If a pilot cannot see the horizon or the ground below, it is difficult to know if the plane is on course, flying straight or turning, and losing or gaining altitude. Cockpit instruments provide this information. In addition, the instruments help pilots carry out various maneuvers without losing altitude or speed and help them land safely.

Measuring flying speed. A plane's speed is measured in several ways. The *indicated air speed* is the speed a pilot reads on an instrument called an *air-speed indicator.* But an air-speed indicator is affected by the changes in temperature and air pressure at different altitudes. As a result, a plane's indicated air speed differs from its *true air speed* and its *ground speed.* True air speed is the speed of the plane in relation to the air

How an airplane is turned

A pilot must use several controls to make a turn. This plane is beginning a right turn. The pilot has raised the right aileron to bank the wing to the right and has also turned the rudder to the right to steady the plane's nose. The lift on the left side of the wing has increased and is pulling the plane around the turn. But in turning, a plane loses lift. The pilot has therefore raised the elevator to increase the angle of attack. The pilot may also need to increase engine power for added thrust.

WORLD BOOK illustration by Tom Morgan; courtesy of Piper Aircraft Corp.

through which it is moving. Ground speed is the speed of the plane in relation to the earth. A pilot can figure true air speed by checking the indicated air speed and the outside air temperature. Because the air is usually colder at higher altitudes, true air speed increases over indicated air speed about 2 percent for every 1,000 feet (300 meters) of altitude. For example, if a plane is flying at 10,000 feet and its air-speed indicator reads 100 mph, the plane's true air speed will probably be about 120 mph. A pilot can use true air speed to figure the ground speed if he or she knows the direction and speed of the wind. For example, if the true air speed is 120 mph and the plane is flying into a 30-mph headwind, the ground speed will be 90 mph.

A plane's *maximum speed,* also called *top speed,* is the fastest speed it can reach in level flight. Its *best rate of climb speed* is the speed at which it climbs the fastest. *Cruising speed* is the most suitable speed for long-distance flight. *Maneuvering speed* is the fastest speed at which an airplane can be flown in maneuvers or in *turbulence* (irregular air flow, often due to stormy weather) without endangering its structure.

Every plane also has a *yellow arc speed* and a *red line speed,* which are shown on the air-speed indicator. The area marked in yellow is a caution area. A pilot should not carry out sudden maneuvers or enter turbulence while flying at speeds in this range. The area marked in red indicates the fastest speed at which the plane can be flown under any conditions.

Every plane has a *stall speed*—the speed at which the wing loses lift. However, the indicated stall speed tells only the speed at which the airplane will stall in level flight. If the plane is turning, its stall speed will be higher than it is in level flight.

Learning to fly. The Federal Aviation Administration (FAA) issues private pilot certificates to qualified United States citizens who are at least 17 years old. A private pilot certificate authorizes a person to fly a plane carrying passengers without payment for his or her services.

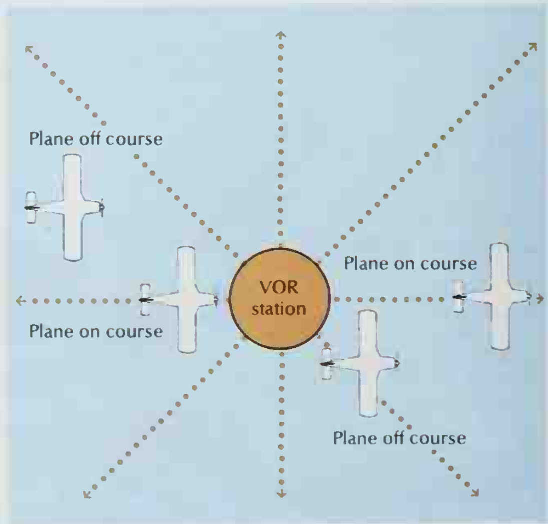
A person who wants to learn to fly must first get a student pilot certificate by passing a simple medical examination. Student pilots may be any age, but they must be at least 16 to fly *solo* (alone).

Student pilots must successfully complete a course of flight instruction consisting of a minimum of 35 to 40 hours of flying time. About half the time is spent in dual flight instruction, with an instructor accompanying the student in the plane. The rest of the time is solo practice flight, with only the student pilot in the plane. Students must complete about half their solo hours in cross-country flights outside their local airport area. Before every cross-country flight, students check the weather and plot their course. Student pilots must also pass both a written examination and a flight examination before being issued a private pilot certificate.

In Canada, the Department of Transport issues private pilot licenses to people who are at least 17 years old and who pass certain physical, written, and flight examinations. A student pilot must have a student pilot permit.

Many student pilots take ground instruction as well as flight instruction. Ground instruction includes courses in aerodynamics, *meteorology* (the study of the weather), navigation, and flying regulations. Students must have good knowledge of all these subjects to pass their pilot examinations. However, students are not required to take formal instruction in these subjects and may, instead, use home-study materials.

Air navigation



Air navigation is the means by which pilots determine their plane's location in the air and direct its route of flight. Pilots use charts, compasses, radio systems, and computerized instruments to navigate accurately.

The three chief methods of air navigation are (1) pilotage, (2) dead reckoning, and (3) radio navigation. Most pilots use a combination of all three methods.

Pilotage, also called *piloting,* is the simplest and most common method of air navigation. Using this method, a pilot keeps on course by following a series of landmarks on the ground. Before take-off, the pilot plots his or her course on an *aeronautical chart,* a map that shows the location of various landmarks, such as bridges, highways, railroad tracks, rivers, and towns. An aeronautical chart also shows routes for aircraft, landing fields, and radio stations that broadcast air navigation signals. The U.S. Department of Commerce publishes such charts for all parts of the United States.

As the plane flies over each landmark on the plotted course, the pilot checks it off on the chart. If the plane does not pass over a landmark, the pilot must adjust the path of flight to resume its preplanned course.

Dead reckoning is a way of navigating when there are few or no visible landmarks. It demands more skill and experience than pilotage does. An aviator uses dead reckoning when flying over forests, deserts, large bodies of water, or heavy clouds. This method of navigation requires an aeronautical chart, an accurate clock, a compass, and a calculator for figuring time, speed, and distance. Working with the chart, the pilot plots a route in advance. The pilot also figures how long it should take to reach the destination while flying at a constant speed.

WORLD BOOK diagram

A VOR station sends out rays of radio signals, or *radials,* in 360 directions. Eight radials are shown here. A pilot selects a radial to follow to or from the station. The plane's VOR equipment indicates whether the plane is on or off the selected course.

The pilot adjusts the course to allow for the wind.

In the air the pilot watches the compass to keep the plane headed in the right direction. The plane should arrive at the destination when it has flown exactly the length of time planned. Dead reckoning is not always a successful method of navigation because changing winds may drive a plane slightly off course.

Radio navigation uses signals broadcast from special radio stations. Electronic equipment on the plane uses these signals to indicate the location and direction of the plane with respect to the transmitting station. Radio navigation is used by almost all pilots, especially in the United States. There are more than 1,000 radio navigation stations throughout the country that guide aircraft en route, plus many other stations for navigation near airports. When pilots fly in or above the clouds, they use the IFR (*I*nstrument *F*light *R*ules) chart, a map of routes between radio navigation stations.

To navigate by radio, pilots first find out from an aeronautical chart what radio station they should tune to in a particular area. The plane's navigation equipment picks up the signal. An indicator needle on the equipment indicates when the plane is flying on a direct course to or from the station. The needle also shows when the plane drifts off course so the pilot can correct its direction. This system, which is designed for *civil* (nonmilitary) aircraft, is called VOR (*V*ery High Frequency *O*mnidirectional *R*ange). Most VOR stations also transmit signals for *DME* (*D*istance *M*easuring *E*quipment). DME tells the pilot how far the aircraft is from the VOR station. Military aircraft use a similar system called TACAN (*TAC*tical *A*ir *N*avigation). A combined civil and military system, called VORTAC, is used by both civil and military planes.

Navigating across oceans requires the use of special systems. Three commonly used systems are (1) *inertial guidance,* (2) *loran* (*lo*ng *ra*nge *n*avigation), and (3) *satellite navigation.* Many planes also use loran and satellite navigation for any flight.

Inertial guidance systems do not rely on any information from outside the vehicle. Instead, a computer and other devices on board provide the guidance information. The devices measure changes in the plane's speed and direction. The computer uses this information to calculate the vehicle's position and to guide it on course.

Loran systems use radio signals sent out continuously from various maritime transmitting stations. Electronic equipment aboard the airplane picks up the signals from at least three stations to determine the plane's location.

Satellite navigation systems use radio signals that are broadcast from artificial satellites orbiting the earth. The signals from at least three satellites are picked up by receivers located on the aircraft. The equipment uses this information to calculate the plane's location based on the distances between the satellites and the receiver. Navigation satellites enable airplanes to determine their locations within 100 feet (30 meters) or better. In the 1990's, thousands of planes began to be outfitted with receivers that provide access to a satellite system called the Global Positioning System (GPS). In the 2000's, satellite navigation will gradually replace loran.

Safety. Airplane pilots follow two sets of rules when flying. When the weather enables them to see clearly, pilots usually follow Visual Flight Rules (VFR). They observe Instrument Flight Rules (IFR) when they cannot see the ground or other aircraft in the sky. However, the U.S. government requires all jet airliners to operate under Instrument Flight Rules at all times.

Pilots have various navigation aids that help them take off, fly, and land safely. In the United States, one of the most important aids is a series of air route traffic control centers operated by the federal government. Each center uses radar to make sure all the planes in its vicinity are clear of other traffic. In addition, airplanes carry a special receiver and transmitter called a *radar transponder.* This device receives a radar signal from a control center and transmits back a code assigned to the plane by the control center. When the signal reaches the ground, it identifies the plane and makes the aircraft

The Boeing Company

A wind tunnel enables aircraft designers and engineers to test how a plane will perform under various flying conditions. Air is forced through the tunnel at high speeds to study the effects of wind and air pressure on a scale model of the plane. This wind tunnel is operated by Britain's Defence Research Agency in Farnborough, near London.

The Boeing Company

Aircraft assembly takes place in some of the largest manufacturing plants in the world, such as this huge facility near Everett, Washington, where the Boeing 777 is manufactured.

show up more clearly on a radar screen, regardless of the plane's size.

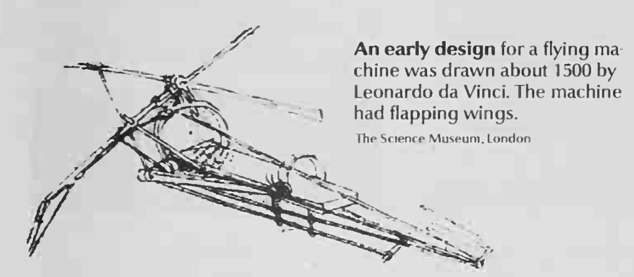
Most large and medium-sized airports also have air traffic control towers. In the towers, air traffic controllers use radio communications and often radar to direct planes that are approaching and landing or taking off and departing. Most larger airports also have an Instrument Landing System (ILS) to guide pilots to the runway in bad weather. This system uses horizontal and vertical radio beams from the ground to operate an instrument in the cockpit of an airliner. By watching this instrument, pilots can tell their exact position in relation to the runway and so can make a safe landing.

Building an airplane

In the United States, the Federal Aviation Administration makes rules for the design and manufacture of airplanes. The agency sets standards that every airplane designer and manufacturer must meet. A manufacturer may not sell a plane until the aircraft receives certification from the FAA. The certification states that the plane meets FAA standards for "design, materials, workmanship, construction, and performance."

Some people build their own airplanes. The FAA sets different standards for home-built planes. Such a plane receives a certification that specifies (1) where and when it may fly and (2) how many passengers it may carry.

Design and testing. Designers and engineers begin to plan and test a new airplane long before it is ready for mass production. Transports and other large planes require at least 8 to 10 years of planning. The design depends largely on how the plane is to be used. Transports must be able to carry heavy loads great distances, using as little fuel as possible. Light planes must be able to maneuver easily and to land on shorter runways. All planes must have a wing that gives great lift at low speed and little drag at high speed. The FAA requires that a wing be joined to the fuselage so firmly that it can produce lift four to six times the force of gravity on the plane. For example, if a plane weighs 2,000 pounds (910 kilograms), its wing must withstand a force of gravity of at least 8,000 pounds (3,600 kilograms).



Engineers carefully test the metal, plastics, wood, and other materials to be used in a plane. All the materials must be able to withstand tremendous air pressures and extreme weather conditions. Engineers may use a structure called a *wind tunnel* to test the effects of air flowing over the plane at various speeds and altitudes. Today, however, many airplane designs are tested using computers instead of wind tunnels. In addition to these tests, engineers build full-sized *mock-ups* (models) of aircraft from wood or metal—often complete in every detail—to test the arrangement of seats and equipment.

After years of planning and research, engineers build a *prototype* (full-sized test model) of the plane. They test it thoroughly on the ground, running the engines at high speed and taxiing the model along a runway as fast as it will go. Usually, engineers build several prototypes to

Flight of Daedalus and Fall of Icarus (1493), a woodcut by an unknown German artist; the Science Museum, London

An ancient Greek story told how Daedalus and his son Icarus flew with wings of feathers and wax. But Icarus flew too near the sun. His wings melted, and he fell into the sea and drowned.

An early design for a flying machine was drawn about 1500 by Leonardo da Vinci. The machine had flapping wings.

The Science Museum, London

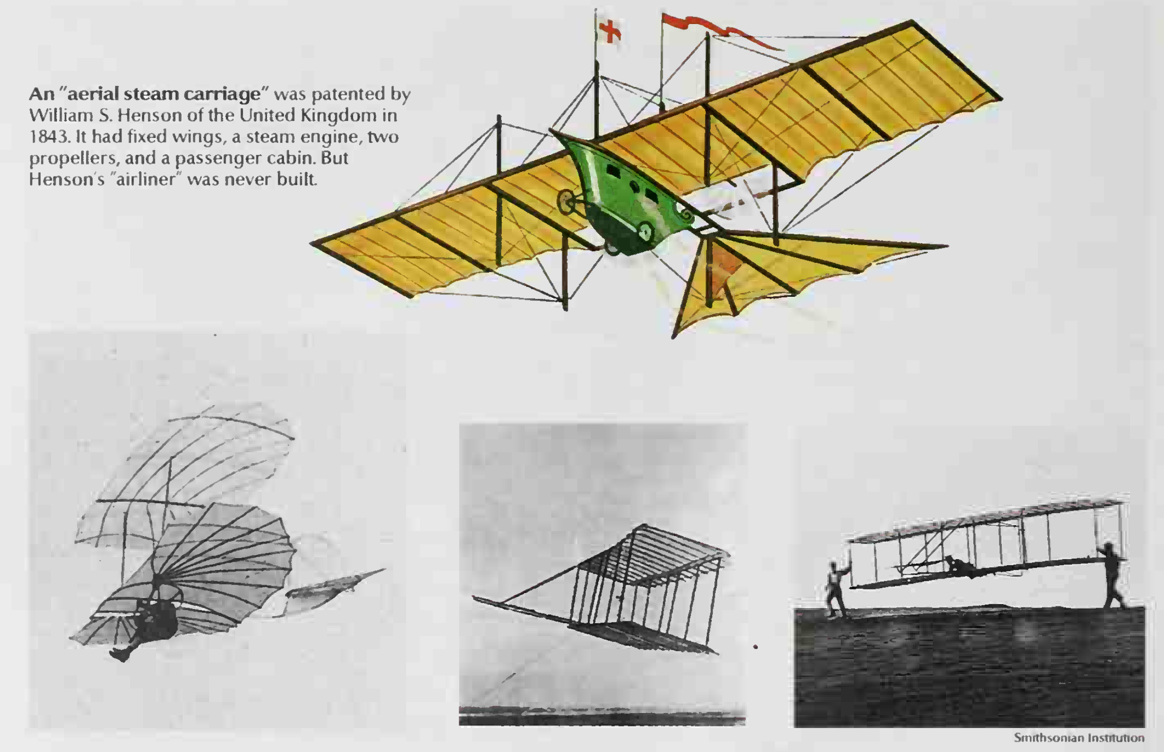
The first human flights were in balloons filled with hot air. This balloon, built by the Montgolfier brothers of France in 1783, carried two passengers about 5 miles (8 kilometers) across Paris.

discover how much wear the plane can take and to test various systems. The engine and other parts on some prototypes are tested until they fail. The manufacturer then tests an experimental plane in flight. Following these procedures, the FAA reviews every aspect of the design, construction, and testing of the aircraft, including the flight testing. If the plane meets the FAA's strict requirements, the agency gives the manufacturer a *type certificate,* which allows the plane to be sold.

The Boeing 777, which entered service in 1995, was completely planned with computers. Instead of making paper drawings or building models, engineers used computers to electronically design and test the entire plane and ensure that the parts would fit together.

Mass production. Only a few companies manufacture airplanes. But thousands of factories supply airplane manufacturers with the parts they need to assemble the planes. Some suppliers specialize in making such parts as fasteners, landing gears, or instruments. Others build the larger parts of the aircraft, including the wing, fuselage, and tail.

An airplane assembly plant operates much like an automobile assembly plant, with workers stationed along an *assembly line,* also called a *production line.* Large plants also have *subassembly lines,* where workers put together large parts of the plane, such as the fuselage and wing, before sending them on for final assembly. The fuselage moves slowly along the final assembly line. It stops at various locations along the line, and workers install or attach the engine, wing, and other parts.



After all the parts of the airplane have been put in place, the finished airplane rolls off the assembly line. Each new plane receives a complete inspection, and a test pilot flies it to make sure the engines and controls are in perfect working order. After the plane passes these final tests, it is ready for delivery to a customer.

History

For thousands of years, people dreamed of flying. Some even tried to fly by tying feathers to their arms and flapping them like wings. But most people believed that flying was beyond the powers of ordinary human beings. They told stories of godlike people who could fly or who were carried through the air by winged animals. The ancient Greeks told a story about an inventor named Daedalus and his son Icarus, both of whom flew with wings made of feathers and wax. But Icarus flew too close to the sun. The sun's heat melted his wings, and he fell into the sea and drowned. See Daedalus.

Early experiments and ideas. About 400 B.C., a Greek scholar named Archytas built a wooden pigeon that moved through the air. No one knows how Archytas made his pigeon fly. He may have attached the bird to a revolving arm and used steam or gas to move it in a circle. During the 300's B.C., the Chinese discovered how to make kites. A kite is really a form of glider. Later, large kites lifted people into the air.

During the 200's B.C., the great Greek mathematician and inventor Archimedes discovered how objects float in liquids. For hundreds of years, people thought their bodies would float or fly in the air, too, if they equipped themselves with such devices as flowing cloaks or artifi-

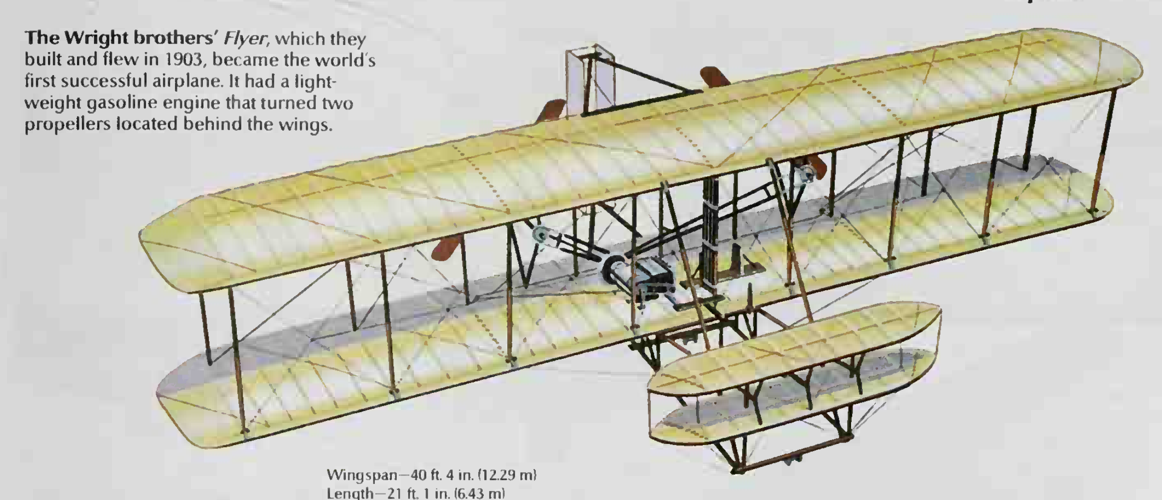
An "aerial steam carriage" was patented by William S. Henson of the United Kingdom in 1843. It had fixed wings, a steam engine, two propellers, and a passenger cabin. But Henson's "airliner" was never built.

Smithsonian Institution

The first glider flights in which a person actually piloted the glider were made in the early 1890's by Otto Lilienthal of Germany. But his gliders were difficult to control.

Improved gliders were built and tested by Orville and Wilbur Wright of the United States. Their first glider, *left,* was a large, two-wing kite built in 1899. After experiments with this and other gliders, the Wright brothers built a glider in 1902 that the pilot could control in the air, *right.*

cial wings. But all of their attempts failed. About A.D. 1290, an English monk named Roger Bacon wrote that air, like water, has something solid about it. Bacon had studied the ideas of Archimedes and concluded that if people could build the right kind of machine, the air would support it, as water supports a ship. About 1500, the Italian artist and inventor Leonardo da Vinci made drawings of *ornithopters,* flying machines with wings designed to flap like those of a bird. In 1680, Giovanni A. Borelli, an Italian mathematician, showed that people cannot fly by flapping wings. Borelli proved that people's muscles are too weak to flap the large surfaces that would be needed to support their weight in the air.



First human flights. In 1783, two Frenchmen—a doctor named Jean F. Pilâtre de Rozier and a nobleman, the Marquis d'Arlandes—made the first free flight in an artificially created device. They floated for more than 5 miles (8 kilometers) over Paris in a large linen and paper balloon. Two French papermakers—the brothers Jacques Étienne Montgolfier and Joseph Michel Montgolfier—had made the balloon, which was filled with hot air from burning wool and straw. The hot air made it rise.

The Montgolfiers made other successful balloons. The flights of these balloons excited other inventors, who soon began to fill their balloons with hydrogen, a gas lighter than air, to make them rise. The balloons were hard to control. But inventors continued their balloon experiments and, during the mid-1800's, developed the airship. The airships had engines and propellers and so were easier to handle than free-floating balloons, whose course could not be controlled. See **Airship; Balloon.**

Meanwhile, other inventors had turned their attention to gliders, which are heavier-than-air aircraft without engines. In 1804, Sir George Cayley, a British inventor, built the first successful glider. It was a small craft that flew without a passenger. Cayley later built successful full-sized gliders. One of these carried his unwilling coachman across a small valley. Cayley also founded the science of aerodynamics and was probably the first person to describe a fixed-wing airplane powered by propellers.

From 1891 to 1896, Otto Lilienthal of Germany made the first successful glider flights in which a person actually piloted the glider. Before the end of the 1800's, other inventors, including Percy Pilcher of Britain and Octave Chanute of the United States, made similar flights. Some of these early gliders were so well built that they carried their pilots hundreds of feet or meters through the air. But gliders were often hard to control. In addition, they were not designed to carry passengers or cargo and so were not a practical means of transportation.

Powered flight. In 1843, William S. Henson, a British inventor, patented plans for the first plane with an engine, propellers, and a fixed wing. But after building one unsuccessful model, he gave up the project. In 1848, his friend John Stringfellow built a small model plane using Henson's design. The model was successfully launched but could stay in the air only a short time. In 1890, Clément Ader, a French engineer, took off in a steam

The Wright brothers' ***Flyer***, which they built and flew in 1903, became the world's first successful airplane. It had a lightweight gasoline engine that turned two propellers located behind the wings.

powered plane that he had built. But he could not control the plane or keep it in the air. About the same time, the inventor Hiram Maxim—an American who had become a British citizen—built a huge steam-powered flying machine. It had two wings, two engines, and two propellers. Maxim tested the plane in 1894. It lifted off the ground briefly but did not actually fly.

During the 1890's, Samuel P. Langley, an American scientist, built a steam-powered model airplane. Langley called his plane an *aerodrome*. In 1896, it flew more than $\frac{1}{2}$ mile (0.8 kilometer) in about $1\frac{1}{2}$ minutes. Langley then built a full-sized aerodrome powered by a gasoline engine. A pilot attempted to fly the airplane on Oct. 7 and on Dec. 8, 1903. Both times Langley's plane was launched into the air from a houseboat on the Potomac River, and both times the airplane crashed into the water.

The Wright brothers. During the 1890's, Orville Wright and Wilbur Wright became interested in flying while operating their bicycle-manufacturing shop in Dayton, Ohio. The brothers read every book about flying they could find. They started building gliders in 1899. The next year, they began making glider flights near Kitty Hawk, North Carolina, an area known for its steady winds and high sand dunes. After conducting many experiments, the brothers worked out a system for controlling an aircraft in flight.

In 1903, the Wright brothers built their first airplane, named the *Flyer*. It was a *biplane* (two-wing plane) with a 12-horsepower (9-kilowatt) gasoline engine that the brothers also built. The wings, which measured 40 feet 4

Important dates in airplane development

c. 1500 The Italian artist and inventor Leonardo da Vinci made drawings of flying machines with flapping wings.

1783 Two Frenchmen—Jean F. Pilâtre de Rozier and the Marquis d'Arlandes—made the first free lighter-than-air ascent. They made the ascent in a hot-air balloon.

1804 Sir George Cayley of Britain flew the first successful model glider.

1843 William S. Henson, a British inventor, patented plans for a steam-driven airplane that had many of the basic parts of a modern plane.

1848 John Stringfellow of Britain built a small model based on Henson's plane. It remained in the air only briefly.

1891-1896 Otto Lilienthal of Germany became the first person to successfully pilot gliders in flight.

1896 Samuel P. Langley of the United States flew a steam-powered model plane.

1903 Orville and Wilbur Wright of the United States made the first engine-powered, heavier-than-air flights, near Kitty Hawk, North Carolina. Their first flight went 120 feet (37 meters) and lasted only about 12 seconds.

1906 Trajan Vuia, a Romanian inventor, built the first full-sized monoplane, but it could not fly.

1909 Louis Blériot of France became the first person to fly across the English Channel.

1913 Igor I. Sikorsky, a Russian inventor, built and flew the first four-engine plane.

1915 The first flight of an all-metal, cantilever-wing plane, the Junkers J 1, took place in Germany.

1927 The Lockheed Vega, a single-engine transport, flew for the first time. It became one of the most popular transport planes of the 1920's and early 1930's.

1936 Douglas DC-3 transport planes entered airline service in the United States. They were the most widely used airliners in the mid-1900's.

1939 The first successful flight of a jet-engine airplane took place in Germany.

1947 Charles E. Yeager, a U.S. Air Force captain, made the first supersonic flight, in a Bell X-1 rocket plane.

1952 De Havilland Comets, the world's first large commercial jetliners, began service.

1953 The North American F-100 Super Sabre jet fighter became the first operational supersonic fighter.

1958 The Boeing 707 began the first U.S. jet transport service between the United States and Europe.

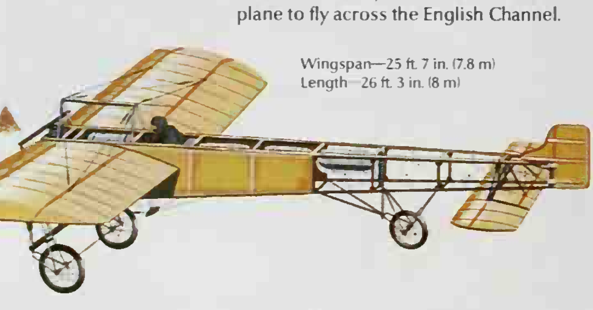
1968 Russian pilots test-flew the world's first supersonic transport plane, the Tu-144.

1970 The first jumbo jet, the Boeing 747, entered service. The 747 became the most widely used airliner of the late 1900's.

1976 The Concorde, a supersonic transport plane built by the United Kingdom and France, began passenger service.

1983 A Rockwell Sabreliner became the first plane to cross the Atlantic Ocean with a pilot guided only by a satellite navigation system.

1995 The Boeing 777 airliner, the world's largest twin-engine jet, began passenger service.

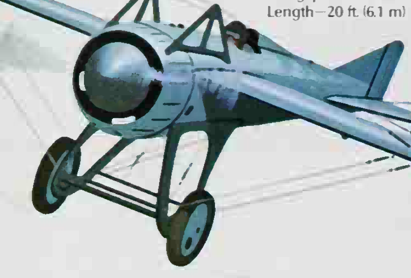


Culver Pictures

Wingspan—42 ft. 6 in. (13.89 m)
Length—30 ft. (9.1 m)

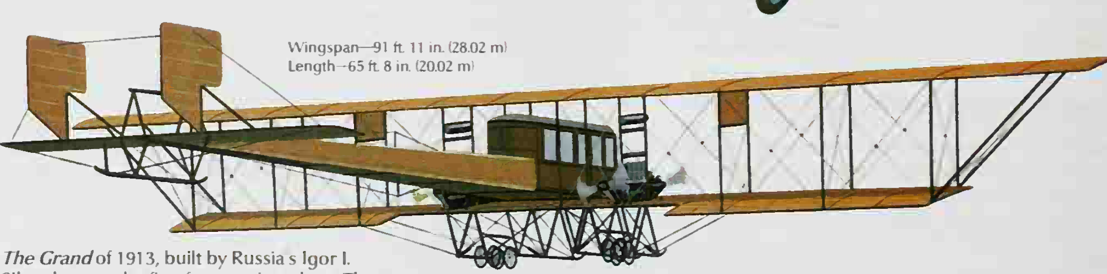
The *June Bug* was designed by Glenn H. Curtiss. In July 1908, Curtiss used the plane to make the first official public airplane flight in the United States. But it was only a short, shaky flight.

The Blériot XI, built and flown by Louis Blériot of France, in 1909 became the first plane to fly across the English Channel.



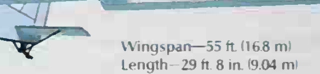
Wingspan—25 ft. 7 in. (7.8 m)
Length—26 ft. 3 in. (8 m)

Wingspan—18 ft. (5.5 m)
Length—20 ft. (6.1 m)



The Demoiselle of 1909 was one of a series of small lightweight planes built in France by Alberto Santos-Dumont, a Brazilian. The Demoiselles were among the first planes used for personal and pleasure flying.

The Deperdussin racer, built in France in 1912, was one of the first planes with a *monocoque* (tubelike) body, reducing the need for body braces and so lightening the plane.

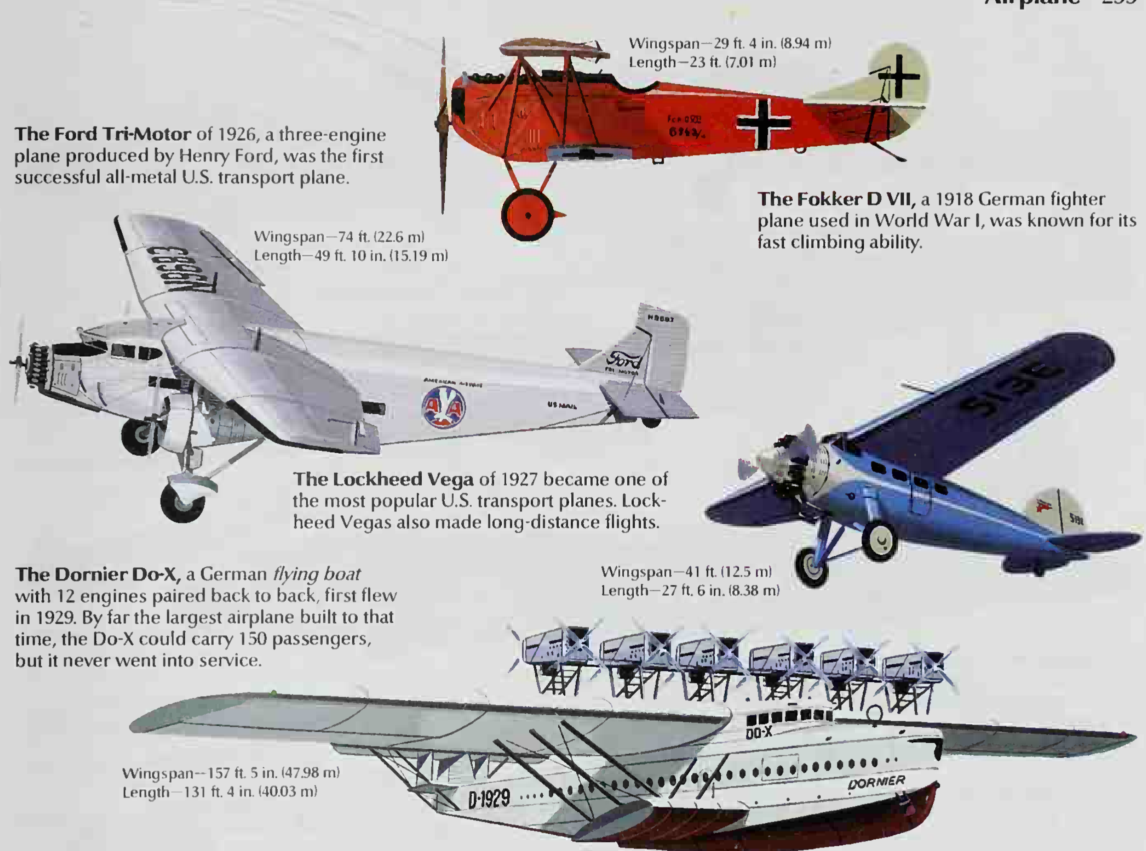


Wingspan—21 ft. 10 in. (6.65 m)
Length—20 ft. (6.1 m)

Wingspan—91 ft. 11 in. (28.02 m)
Length—65 ft. 8 in. (20.02 m)

The Grand of 1913, built by Russia s Igor I. Sikorsky, was the first four-engine plane. The engines were paired back to back.

The Junkers J 1, built in Germany in 1915, was the first plane with an all-metal body and a *cantilever* wing, which is supported by an internal framework instead of outside braces.



Wingspan—55 ft. (16.8 m)
Length—29 ft. 8 in. (9.04 m)

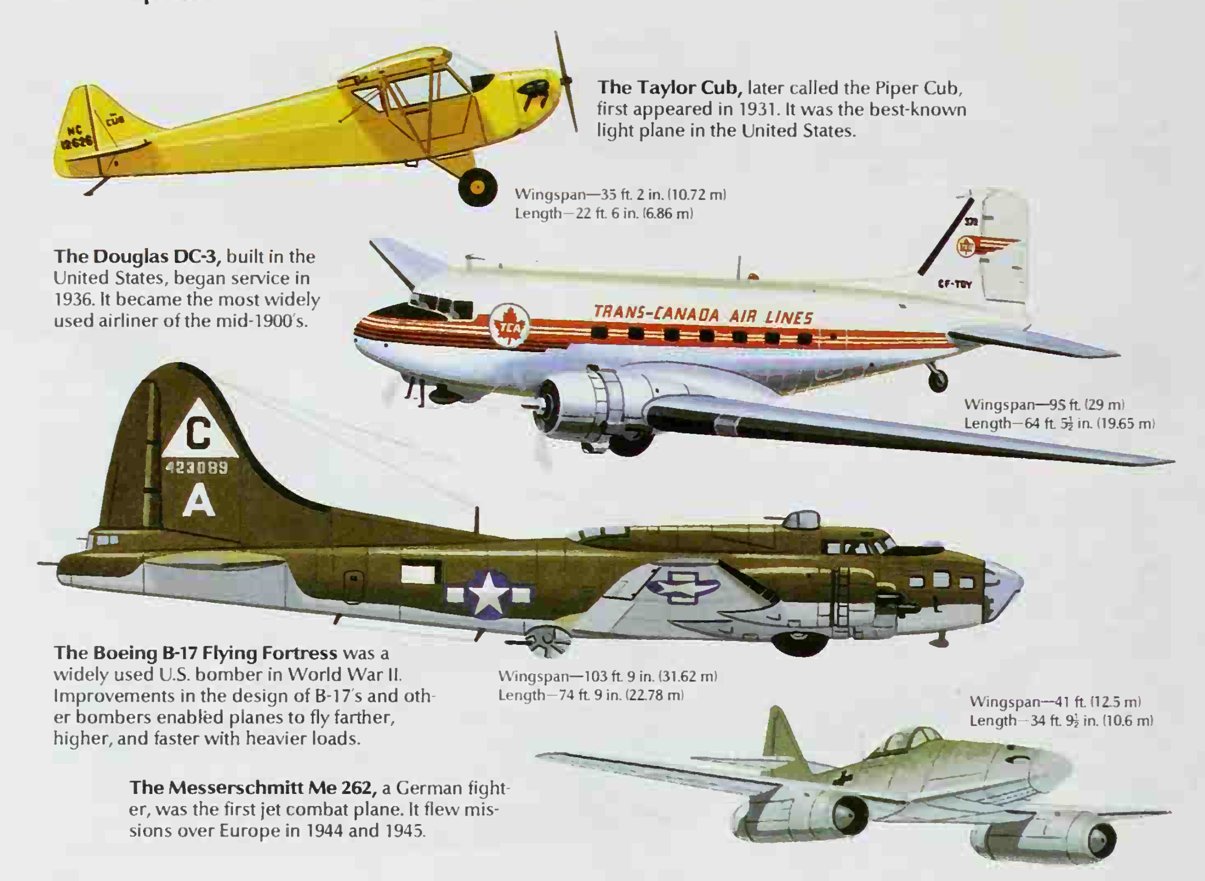
The Ford Tri-Motor of 1926, a three-engine plane produced by Henry Ford, was the first successful all-metal U.S. transport plane.

The Fokker D VII, a 1918 German fighter plane used in World War I, was known for its fast climbing ability.

The Lockheed Vega of 1927 became one of the most popular U.S. transport planes. Lockheed Vegas also made long-distance flights.

The Dornier Do-X, a German *flying boat* with 12 engines paired back to back, first flew in 1929. By far the largest airplane built to that time, the Do-X could carry 150 passengers, but it never went into service.



inches (12.29 meters) from tip to tip, were wooden frames covered with cotton cloth. The pilot lay in the middle of the lower wing. The engine, mounted to the pilot's right, turned two wooden propellers located behind the wings. Instead of wheels, the plane had wooden runners. Most important of all, it had the successful control system that the brothers had developed for their gliders. A main feature of this system, called a *wing warp system,* was a device for twisting the wing tips to preserve balance in flight. The device consisted of a wire strung from each wing tip to a "cradle" that fitted around the pilot's hips. By moving their hips, the brothers could twist one wing tip or the other in order to maintain the plane's balance and control while in flight.

On Dec. 17, 1903, Orville Wright became the first person to successfully fly an engine-driven, heavier-than-air machine. The flight took place near Kitty Hawk. The brothers launched the plane from a 60-foot (18-meter) rail on a sand flat. The plane took off and flew 120 feet (37 meters) at about 30 mph (48 kph). The flight lasted only about 12 seconds. The Wright brothers made three more flights that day. Wilbur made the longest one—852 feet (260 meters) in 59 seconds.

Except for a few inventors, most people took little notice of the Wright brothers' achievement. But the men continued to improve their planes. By the end of 1905, they had built and flown the first plane that was fully maneuverable and could fly for more than a half hour at a time. But no important officials had seen the plane fly, and so the flights were not officially recognized. In 1908, Wilbur made the first official public flights in France and amazed the world with the plane's flying ability.

Other pioneer planes and fliers. Alberto Santos-Dumont, a Brazilian who lived in France, became the third person to fly an airplane. In 1906, he made a few brief flights in a plane patterned after a box kite. He later built a series of planes that were among the first used for personal and pleasure flying. Also in 1906, Trajan Vuia, a Romanian inventor living in France, constructed the first full-sized *monoplane* (single-wing plane). It had the propeller mounted in front of the wing rather than behind. Although the plane was unsuccessful, it influenced the design of later airplanes.

Glenn H. Curtiss, an American inventor, made the first important airplane flight in the United States after the Wright brothers. On July 4, 1908, he became the first American to make an official public flight of more than 1 kilometer (0.6 mile). He flew his biplane, the *June Bug,* 5,090 feet (1.55 kilometers) at 34 mph (55 kph). Henri Farman, an English flier living in France, had made a circular flight of 1 kilometer earlier in 1908. Then, on Oct. 30, 1908, Farman flew 16$\frac{3}{4}$ miles (27.0 kilometers) directly across the French countryside in the first cross-country flight. The Wright brothers had made longer circular flights. Curtiss, Farman, and the Wright brothers all became successful airplane manufacturers. John A. D. McCurdy, a Canadian engineering student, made the first successful airplane flight in Canada. On Feb. 23, 1909, he flew his biplane—the *Silver Dart*—over $\frac{1}{2}$ mile (0.8 kilometer) across Bras d'Or Lake in Nova Scotia.

The Taylor Cub, later called the Piper Cub, first appeared in 1931. It was the best-known light plane in the United States.

Wingspan—35 ft. 2 in. (10.72 m)
Length—22 ft. 6 in. (6.86 m)

The Douglas DC-3, built in the United States, began service in 1936. It became the most widely used airliner of the mid-1900's.

Wingspan—95 ft. (29 m)
Length—64 ft. 5½ in. (19.65 m)

The Boeing B-17 Flying Fortress was a widely used U.S. bomber in World War II. Improvements in the design of B-17's and other bombers enabled planes to fly farther, higher, and faster with heavier loads.

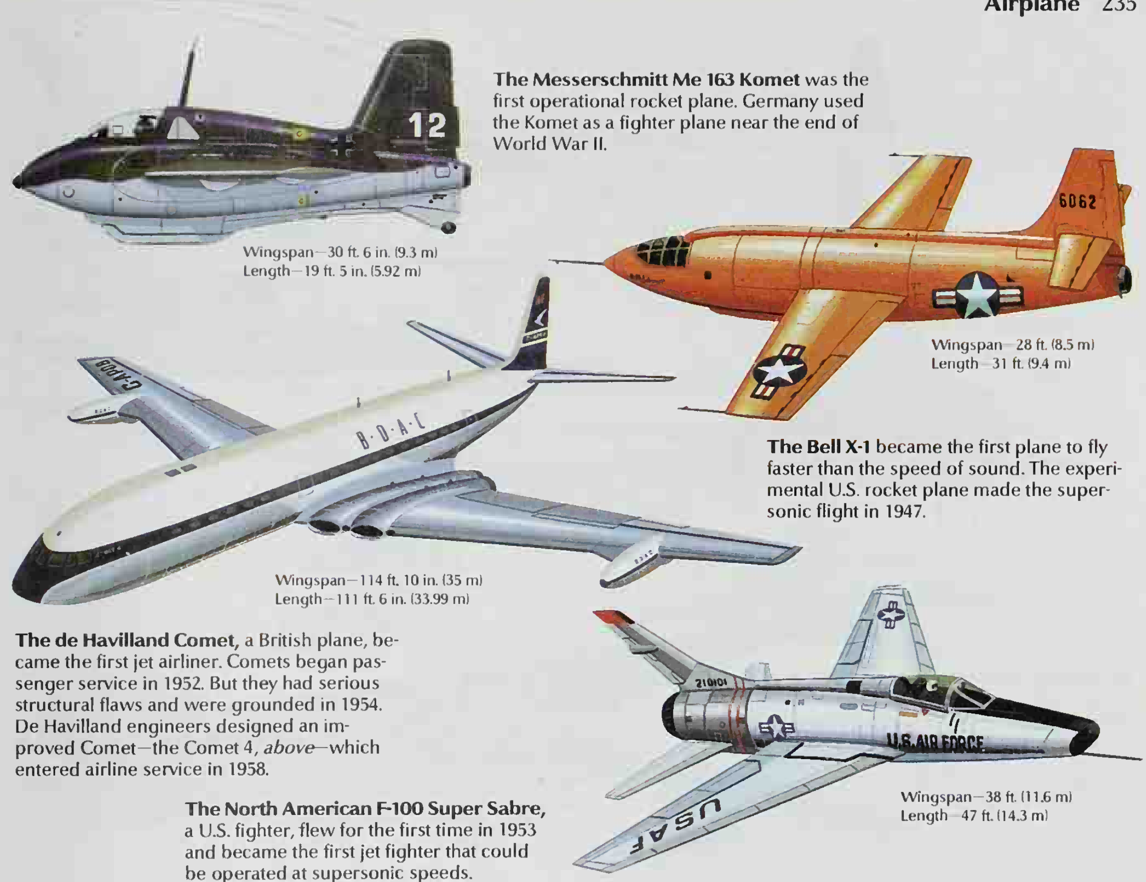
Wingspan—103 ft. 9 in. (31.62 m)
Length—74 ft. 9 in. (22.78 m)

The Messerschmitt Me 262, a German fighter, was the first jet combat plane. It flew missions over Europe in 1944 and 1945.

Wingspan—41 ft. (12.5 m)
Length—34 ft. 9½ in. (10.6 m)

Thomas E. Selfridge, a lieutenant in the U.S. Army Signal Corps and the first officer trained to fly, was the first person killed in a plane crash. The Army had decided to test the military value of the Wright brothers' airplane. On Sept. 17, 1908, Selfridge went up in a plane with Orville Wright. At an altitude of 75 feet (23 meters), one of the two propellers broke. The plane crashed, killing Selfridge and injuring Wright. But the Wrights were not discouraged. In 1909, they won an Army contract to build the world's first military plane.

A French inventor, Louis Blériot, made the first international airplane flight. In 1909, he flew his *Blériot XI* monoplane 23½ miles (37.8 kilometers) across the English Channel from France to England. The plane had a long, enclosed body, a tail for control at the rear, and a wheeled landing gear. Other successful monoplanes of the period included the *Antoinette* series designed by the French inventor Leon Levavasseur.



In 1911, Calbraith P. Rodgers made the first airplane flight across the United States—from Sheepshead Bay, New York, to Long Beach, California. During the 84-day journey, Rodgers landed—or crashed—his Wright airplane about 70 times. He had to replace almost every part of the plane before he reached Long Beach. His actual flying time was 3 days 10 hours 24 minutes.

In 1912, the Deperdussin Company of France built the Deperdussin monoplane racer, the first successful airplane of *monocoque* construction (pronounced *maw naw KAWK* or *MAHN uh kohk*). In this type of construction, the fuselage of the plane consisted of a structure strong enough to bear the stresses of flight, reducing the need for external bracing. The monocoque design produced a streamlined aircraft that was lighter and created less drag. Meanwhile, two-engine planes had been developed. In 1913, a Russian inventor, Igor I. Sikorsky, flew his *Russky Vityaz* (Russian Knight), also called *The Grand,* the first four-engine plane. Most planes still had one engine.

The early fliers and their planes participated in many air races and air circuses. These tests of flying skill did much to improve airplane design and to make flying more popular. In 1913, a French pilot, Adolphe Pégoud, became noted for his skill at air acrobatics.

World War I (1914-1918) greatly advanced airplane development. Early in the war, both sides discovered the value of the airplane for locating enemy forces and military bases. Engineers designed more powerful engines to put swift fighter planes and heavy bombers into the skies. Germany, France, and Britain began to turn out thousands of these planes. *Dogfights* (air battles between fighters) became common. Seaplanes were used for taking pictures of enemy naval forces and for bombing enemy submarines. For the story of how airplanes were used in World War I, see **Air Force** (World War I); **World War I.**

At the beginning of the war, most planes could fly 60 to 70 mph (97 to 110 kph). By the war's end, many could go 130 mph (209 kph) or faster. Hugo Junkers, a German inventor and manufacturer, created one of the most influential airplane designs of the war. His plane, called

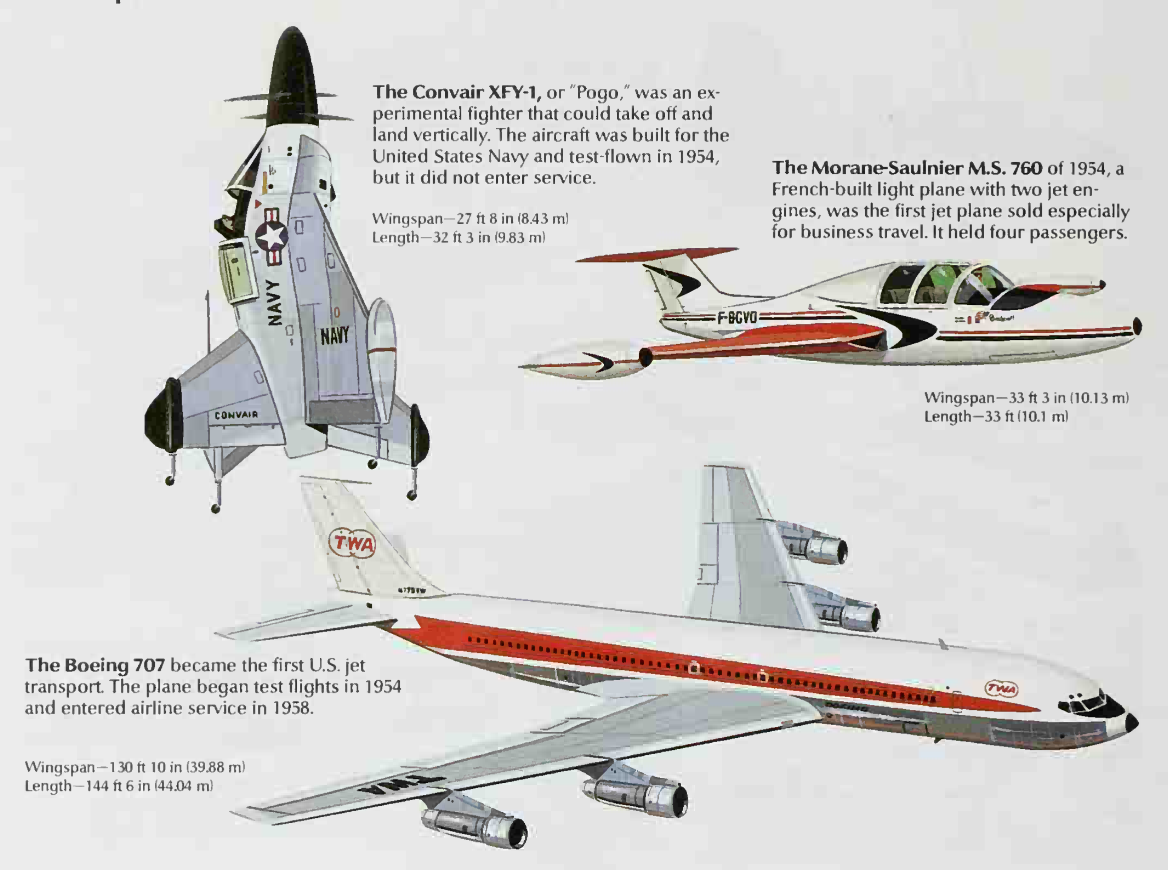
The Messerschmitt Me 163 Komet was the first operational rocket plane. Germany used the Komet as a fighter plane near the end of World War II.

The Bell X-1 became the first plane to fly faster than the speed of sound. The experimental U.S. rocket plane made the supersonic flight in 1947.

The de Havilland Comet, a British plane, became the first jet airliner. Comets began passenger service in 1952. But they had serious structural flaws and were grounded in 1954. De Havilland engineers designed an improved Comet—the Comet 4, *above*—which entered airline service in 1958.

The North American F-100 Super Sabre, a U.S. fighter, flew for the first time in 1953 and became the first jet fighter that could be operated at supersonic speeds.

the Junkers J 1, made its first flight in 1915. The plane was the first to be made entirely of metal and the first to have a cantilever wing, which is completely supported by an internal framework. Earlier airplane wings were supported by *struts* (braces) between the body and wings, which created drag and reduced the airplanes' speed.



The golden age in the development of the airplane occurred during the 1920's and 1930's. During this period, rapid advances were made in airplane design, and airlines began large-scale operations. It was also a time when daring pilots amazed the world with feats of flying skill and endurance.

In 1914, an American flier named Tony Jannus was the pilot of the world's first scheduled airline. Jannus used a small seaplane to carry passengers and freight across Tampa Bay between St. Petersburg and Tampa, Florida. The plane had room for one passenger, who paid $5 for the 22-mile (35-kilometer) flight. The airline had financial difficulties and lasted only a few months. In 1919, small airlines began to operate in Europe. They used rebuilt World War I bombers to carry passengers and mail on short flights between European cities. The cabins of some of the planes were elegantly decorated and furnished with comfortable armchairs. But the passengers could barely make themselves heard above the roar of the engines, and the cabins were unheated.

After World War I, the U.S. government offered thousands of surplus warplanes for sale at bargain prices. Although these planes were stronger than those built before the war, they still were not always safe. They were made mostly of wood and cloth and lacked satisfactory navigation equipment. But many former military pilots bought the planes and used them for an exciting and dangerous type of flying called *barnstorming*. Barnstormers toured the United States in the 1920's and put on daring air shows at county fairs and other events. The pilots flew the planes in wild acrobatics. Performers called *wing walkers* stepped from wing tip to wing tip in flight, or leaped from the wing of one flying plane to another. Many of the planes crashed, and a number of barnstormers were killed.

The United States Post Office, the forerunner of the U.S. Postal Service, also used modified military planes to fly mail between a few large cities. The Post Office began airmail service in 1918, operating its own planes. By 1927, the Post Office gave up operating its own planes and contracted with the airlines to carry airmail. Airmail greatly aided the growth of commercial aviation.

Meanwhile, engineers were working to design safer, more powerful transport planes. German engineers developed an all-metal, *trimotor* (three-engine) transport, the Junkers G 23. It flew for the first time in 1924 and was the first of a series of all-metal, trimotor planes made in Europe. The first such plane in the United States was developed from the ideas of William B. Stout, an aircraft manufacturer. Henry Ford, the automobile maker, bought Stout's company and began producing a trimotor plane in 1926. The Ford Tri-Motor could carry 10 pas-

The Convair XFY-1, or "Pogo," was an experimental fighter that could take off and land vertically. The aircraft was built for the United States Navy and test-flown in 1954, but it did not enter service.

Wingspan—27 ft 8 in (8.43 m)
Length—32 ft 3 in (9.83 m)

The Morane-Saulnier M.S. 760 of 1954, a French-built light plane with two jet engines, was the first jet plane sold especially for business travel. It held four passengers.

Wingspan—33 ft 3 in (10.13 m)
Length—33 ft (10.1 m)

The Boeing 707 became the first U.S. jet transport. The plane began test flights in 1954 and entered airline service in 1958.

Wingspan—130 ft 10 in (39.88 m)
Length—144 ft 6 in (44.04 m)

sengers at 100 mph (160 kph) or more. In 1927, the Lockheed Company (now Lockheed Martin Corporation) produced the Vega, a single-engine transport that carried up to six passengers. It could fly 135 mph (217 kph) and travel 500 miles (800 kilometers) or farther without refueling. The Ford Tri-Motor and the Lockheed Vega were among the most popular transport planes of the late 1920's and early 1930's.

Races helped encourage improvements in airplane design during the 1920's and 1930's. Important races in

Notable airplane flights

1908 Henri Farman of France made the first official circular flight of 1 kilometer (0.6 mile). He also flew 16.75 miles (27.0 kilometers) in the first cross-country flight.

1908 Glenn H. Curtiss made the first official public flight of more than 1 kilometer in the United States.

1911 Calbraith P. Rodgers made the first flight across the United States. He flew from Sheepshead Bay, New York, to Long Beach, California, in a series of short flights that took 84 days.

1919 Two British fliers, John Alcock and Arthur Whitten Brown, made the first nonstop transatlantic flight. They flew 1,950 miles (3,138 kilometers) from St. John's, Newfoundland, to Clifden, Ireland.

1924 Two U.S. Army planes made the first round-the-world flight. They took nearly six months to complete the 26,345-mile (42,398-kilometer) journey.

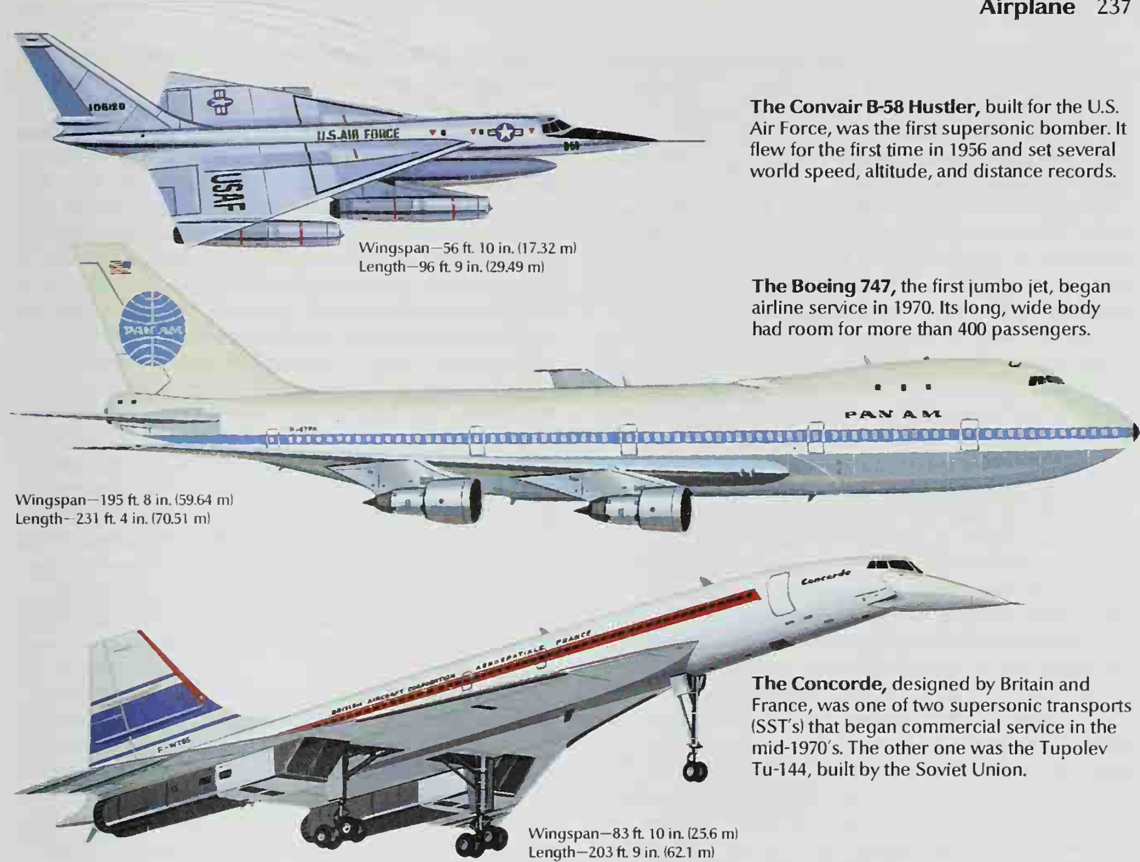
1926 American explorers Richard E. Byrd and Floyd Bennett claimed the first airplane flight over the North Pole.

1927 Charles A. Lindbergh, a U.S. pilot, made the first solo nonstop transatlantic flight. He flew 3,610 miles (5,810 kilometers) from Garden City, New York, to Paris in 33 hours 31 minutes.

1928 Charles Kingsford Smith and his crew made the first flight across the Pacific—from Oakland, California, to Brisbane, Australia, with stops at Honolulu, Hawaii, and Suva, Fiji.

1929 Richard E. Byrd of the United States and his crew made the first flight over the South Pole.

1931 Two U.S. pilots, Clyde Pangborn and Hugh Herndon, made the first nonstop airplane flight across the Pacific. They flew from Tokyo to Wenatchee, Washington.



1932 Amelia Earhart of the United States was the first woman to fly across the Atlantic Ocean alone. She flew from Harbour Grace, Newfoundland, to a pasture near Londonderry, Northern Ireland, in 15 hours 18 minutes.

1933 Wiley Post, a U.S. pilot, made the first solo round-the-world flight, traveling 15,596 miles (25,099 kilometers) in 7 days 18 hours 49 minutes.

1949 A U.S. Air Force crew made the first nonstop round-the-world flight, covering 23,452 miles (37,742 kilometers) in 3 days 22 hours 1 minute.

1992 French pilots Claude Delorme and Jean Boyé flew an Air France Concorde around the world in a record 32 hours 49 minutes 3 seconds.

2001 A solar-powered, propeller-driven airplane set an unofficial altitude record of 96,500 feet (155,302 meters). The craft, owned by NASA, was remotely piloted from the ground.

The Convair B-58 Hustler, built for the U.S. Air Force, was the first supersonic bomber. It flew for the first time in 1956 and set several world speed, altitude, and distance records.

The Boeing 747, the first jumbo jet, began airline service in 1970. Its long, wide body had room for more than 400 passengers.

The Concorde, designed by Britain and France, was one of two supersonic transports (SST's) that began commercial service in the mid-1970's. The other one was the Tupolev Tu-144, built by the Soviet Union.

cluded the Pulitzer Trophy races for small planes and the Schneider Trophy races for seaplanes. In 1920, the winner of the Schneider Trophy race flew at 107 mph (172 kph). The 1931 winner reached 340 mph (547 kph).

Fliers of the golden age. A number of American pilots made daring long-distance flights during the 1920's and early 1930's. Richard E. Byrd and Floyd Bennett are credited with flying the first plane to the North Pole, in May 1926. They flew a trimotor plane designed by the Dutch engineer Anthony Fokker. Fokker had built planes in Germany during World War I but moved his plant to the Netherlands after the war. In 1929, Byrd and Bernt Balchen made the first flight over the South Pole, in a Ford Tri-Motor. In 1927, Charles A. Lindbergh made the first solo nonstop flight across the Atlantic Ocean. His 3,610-mile (5,810-kilometer) flight—from Garden City, New York, to Paris—took $33\frac{1}{2}$ hours. Lindbergh's plane, the *Spirit of St. Louis,* was a specially built Ryan monoplane with a Wright engine. It was a little larger than the Wright brothers' first airplane. It also had the most advanced aircraft instruments of the day, which helped Lindbergh find his way across the ocean without a radio.

In 1931, Hugh Herndon and Clyde Pangborn made the first nonstop flight across the Pacific. The next year, Amelia Earhart, flying an improved Lockheed Vega, became the first woman to cross the Atlantic solo and nonstop. In 1933, a former parachute jumper named Wiley Post flew a Vega in the first solo round-the-world flight.

Engineering improvements during the 1930's made it possible to build bigger planes that could fly faster, farther, and higher—and could carry heavier loads. Advances in aerodynamics helped engineers streamline planes so they could cut through the air with as little drag as possible. Engineers designed *controllable-pitch* propellers, with which pilots could set the propeller blade at the best angle for a particular air speed or altitude. Improved radio equipment enabled pilots to receive flight directions from the ground. Automatic pilot devices also came into use during the 1930's. These devices made possible more accurate navigation and enabled pilots to take rest breaks during long flights.

All the major advances in airplane design went into making the Douglas DC-3. This twin-engine transport made its first passenger flights in 1936. The DC-3 could carry 21 passengers and fly smoothly at 200 mph (320 kph). It soon became the most widely used airliner.

During the 1930's, many airline passengers traveled on *flying boats,* large, watertight seaplanes that could float in the water like the hull of a ship. Flying boats were used mainly for flights across oceans. One of the largest commercial flying boats was an enormous 12-engine plane built in Germany—the Dornier Do-X. It flew for the first time in 1929 but never became a popular airliner. One of the last and most famous flying boats was the Boeing 314 Clipper, which could carry up to 74 passengers. In 1939, 314's started the first regular passenger service across the Atlantic Ocean. But the development of more powerful landplanes—and of more airports with runways long enough to handle them—ended the day of the flying boats in most parts of the world.

As planes flew higher and higher, pilots and passengers had increased difficulty breathing in the thin air at high altitudes. So engineers designed *pressurized cabins,* in which the air inside is compressed at high altitudes to make breathing easier. Pressurized cabins became common in the late 1940's.

During World War II (1939-1945), Britain, Germany, Japan, the United States, and other countries turned out thousands of military planes. As in World War I, engineers made great advances in the design of bombers and fighters. Bombers developed during World War II could carry twice as heavy a load and travel nearly twice as far without refueling as prewar bombers could. Early in the war, fighter planes could reach a top speed of 300 mph (480 kph) and climb to about 30,000 feet (9,100 meters). By the end of the war, they were flying more than 400 mph (640 kph) and climbing to over 40,000 feet (12,000 meters). Jet fighters could fly even faster, though they were not used until late in the war. In 1939, Germany made the first successful jet plane flight. The Messerschmitt Me 262 was the first jet to fly combat missions. It flew them over Europe in 1944 and 1945. This fighter could fly nearly 550 mph (885 kph). The Bell Aircraft Company (now a division of Textron Incorporated) built the first U.S. jet plane in 1942.

German scientists had experimented with rocket planes as far back as 1928. Early in World War II, they developed the prototype Messerschmitt Me 163. This rocket-powered plane could fly at over 600 mph (970 kph). German engineers used it as a model for a fighter, the Me 163 Komet, which flew missions late in the war.

Transoceanic transports. Near the end of World War II, manufacturers began to develop nonstop transoceanic transports for commercial airlines. Four-engine transports developed during the war, such as the pressurized Douglas DC-4 and the Lockheed Constellation, were widely used for long-distance commercial passenger service after the war. But they had to stop for refueling on the longest ocean flights. Nonstop transoceanic flights required more powerful engines. By 1945, jet engines had the necessary power, but they used so much fuel that a jet plane could fly only a short distance without refueling. Instead of waiting for improved jet engines, the airlines built more powerful reciprocating engines. Two U.S. manufacturers created reciprocating engines of more than 3,000 horsepower (2,200 kilowatts) for the new transoceanic transports. These engines were used in the Douglas DC-7, the Lockheed Super Constellation, and the Boeing 377 Stratocruiser. Each plane could carry about 100 passengers nonstop between New York City and Paris at over 300 mph (480 kph).

The jet age. During the late 1940's, engineers worked to improve the crude jet engines built during World War II. The Soviet Union and the United States wanted jet engines to increase the power and speed of their bombers and fighters. By the time of the Korean War (1950-1953), both countries had highly effective jet planes. These planes included two famous fighters—the U.S. Air Force F-86 Sabre and the Soviet MiG-15.

In Britain, engineers produced the world's first large commercial jet airliner, the de Havilland Comet. Comets began passenger service in 1952. They flew at nearly 500 mph (800 kph) with little vibration or noise. The cabin was pressurized for safety and comfort. Then, in two separate accidents in January and April 1954, Comets tore apart in the air, killing everyone aboard. The fault proved to be in the plane's metal skin, which was too weak to withstand the stress of pressurization. The disasters led to the development of fuselage designs and structures more suited to pressurization in all airliners, including new Comets. Meanwhile, Britain had also produced the Vickers Viscount, a transport plane with propellers driven by jet engines. These turboprop planes began to carry passengers in 1953.

By the mid-1950's, U.S. engineers were also designing commercial jet airliners. In 1958, the Boeing 707, a four-engine jetliner, began passenger service between the United States and Europe. By 1960, two other U.S. jet transports—the Douglas DC-8 and the Convair 880—had begun passenger service. United States manufacturers also began to design a large jet that could carry several hundred passengers or 50 to 100 short tons (45 to 90 metric tons) of cargo. The first of these giants, the Lockheed C-5A Galaxy military transport, began service in the U.S. Air Force in 1969. The world's first commercial jumbo jet, the Boeing 747, began service in 1970. It could carry more than 400 passengers. Newer versions of the Boeing 747 can travel longer distances, flying 14 hours or more without refueling.

Supersonic airplanes are among the newest developments in air transportation. These planes can fly faster than sound. At sea level, sound has a speed of about 760 mph (1,225 kph). But the speed of sound declines with altitude. At about 50,000 feet (15,250 meters), for example, sound normally travels at about 660 mph (1,060 kph). No early jet plane was powerful enough or sturdy enough to fly faster than sound. A few approached this speed. When they did, shock waves tore the planes apart.

About 1943, U.S. engineers began work on rocket research planes for supersonic flight. These planes had to withstand the terrific air pressures at *Mach 1* (the speed of sound). In 1947, the Bell X-1 rocket plane, piloted by Charles E. Yeager, a U.S. Air Force captain, made the first supersonic flight in history. In 1962, the North American X-15 rocket plane soared 314,750 feet (95,936 meters)—over 50 miles (80 kilometers) above the earth. Robert H. White, an Air Force major, piloted the plane. White thus became the first pilot to qualify as an astronaut by flying an airplane into space. In 1963, the X-15 raised the altitude record to 354,200 feet (107,960 meters)—about 67 miles (108 kilometers) above the earth. Later, it flew faster than Mach 6 (six times the speed of sound). Speeds of Mach 5 (five times the speed of sound) or higher are called *hypersonic.*

Meanwhile, engineers had developed jet engines capable of supersonic speeds. In 1953, the North American F-100 Super Sabre jet fighter became the first jet that could be operated at supersonic speeds in level flight. The first supersonic bomber was the U.S. Air Force's Convair B-58 Hustler. It flew for the first time in 1956.

At first, all the new supersonic jets were military planes. Then in 1968, Soviet test pilots flew the world's first supersonic transport (SST), the Tupolev Tu-144. Britain and France cooperated to build an SST, the Concorde, which made its first test flight in 1969.

The Soviet Union began cargo service with the Tupolev Tu-144 in 1975 and started passenger service in 1977. But in 1983, the Soviet Union withdrew the plane

from service because of technical and operational problems. Britain and France began passenger service to the United States with the Concorde in 1976. But all flights were suspended in 2000 after the crash of a Concorde in France following take-off. Traveling by supersonic airliner has been very expensive because the planes have carried few passengers and have used large amounts of fuel. The planes were also very noisy, so some countries, including the United States, had restricted the Concorde to oceanic flights only.

Future developments. Engineers continue to search for ways to make airplanes faster, safer, quieter, and more efficient. One possible type of future airplane, called a *spaceplane* or *reusable launch vehicle* (RLV), would be powered by rocket engines. Spaceplanes could be launched into Earth's orbit and return to Earth and land on a runway. While in orbit, they would cruise at speeds of up to Mach 15 (15 times the speed of sound). Drew Steketee and F. Robert van der Linden

Control-line model airplanes, *above,* have long wires attached to them. A person controls the flight of such a plane by holding onto the wires as the model whirls around.

Airplane, Model, is a miniature airplane. It may be a copy of a full-sized plane or have an original design. Building model airplanes is a popular hobby. There are flying and nonflying miniature aircraft of all types, including gliders, helicopters, and commercial and military planes. Scientists also use scale models of aircraft for testing before full-sized planes are built. They test the models in *wind tunnels,* which duplicate the air pressure and weather conditions of actual flight. See **Airplane** (Design and testing); **Wind tunnel.**

Models may be powered by twisted rubber bands, electric motors, gas or diesel engines, carbon dioxide, or compressed air. Most model planes take off under their own power, but some are thrown into the air.

In the mid-1980's, over 100,000 people and more than 1,900 model airplane clubs belonged to the Academy of Model Aeronautics (AMA). This organization regulates official model airplane contests in the United States. It also certifies flying records. Contest events include competitions for distance, height, speed, and time aloft.

Hobbyists generally build model airplanes from kits sold by hobby stores. Most kits of nonflying models consist of plastic parts that the modeler glues together. Balsa wood ranks as the most popular material for flying models because it is so light, strong, and easy to work with. Various kinds of synthetic materials may be used for parts of a model that require extra strength, such as the propeller and engine mounts. Hobbyists also build models from plans published in books and magazines. Advanced modelers may design their own planes. Some planes can be purchased assembled and ready to fly.

There are five main kinds of model airplanes. They are (1) display, (2) indoor, (3) free-flight, (4) control-line, and (5) radio control.

Display models cannot fly. Hobbyists build them with the goal of duplicating the appearance of full-

WORLD BOOK photos

A free-flight model airplane, *above,* has no wires. A small engine powers this and many other flying model planes.

A radio control glider called a *sailplane* is about to go airborne, *left.* Radio control models are controlled by a transmitter that sends radio signals to a tiny receiver in the model. The receiver decodes the signals and feeds the information to electric motors. The motors control the surfaces on the wings and tail assembly, allowing the model to maneuver.

Academy of Model Aeronautics

sized aircraft in every possible detail. Some display models have movable propellers, doors, and landing gear. Hobbyists take care in painting these models to make them look authentic. The models are judged at exhibitions on the basis of workmanship and accuracy of detail. Display models make attractive decorations in a home. Modelers may display their planes by arranging them on shelves, hanging them from the ceiling by wires, or exhibiting them in display cases.

Indoor models are flown only inside a building. They fly slowly, and some can stay aloft as long as 45 minutes. An indoor model is powered by twisted strands of rubber that turn the propeller as they unwind. These airplanes have a balsa frame covered by thin paper or a substance called *microfilm.* Microfilm is made by mixing lacquer and castor oil and floating the mixture on water to form a clear, thin film. The modeler removes the film with a wire loop and applies it to the plane's frame. Such models weigh $\frac{1}{30}$ ounce (1 gram) or less. They are too fragile to be flown outdoors, where they might collapse at the slightest movement of air. Indoor gliders are typically made entirely of balsa.

Free-flight models may be powered by rubber strands or have a piston engine. Engine-powered free-flight models run on a mixture of methyl alcohol, nitromethane, and a lubricant. Diesel engines, using a mixture of kerosene, ether, and castor oil, are also used and so are electric motors with rechargeable batteries. Such models built for competitive flying typically have wings from 3 to 6 feet (0.9 to 1.8 meters) long. After launching, a free-flight model climbs straight up for 5 to 15 seconds. A timing device then turns the engine off, and the plane goes into a slow glide for 3 to 5 minutes. Some engine-powered free-flight models that do not have a timing device can fly in a circular pattern for hours. Flying in rising air currents called *thermals* helps them remain airborne.

A free-flight glider may be hand-launched or it may be towed at the end of a cord—100 feet (30 meters) or more—and released. Such gliders have remained airborne for many hours by flying in rising thermals.

Control-line models have piston or jet engines and fly at the end of wires. Most control-line models have two Dacron or steel wires that measure from 25 to 75 feet (8 to 23 meters) long. One end of each wire is attached to the model and moves the plane's *elevator,* a control surface on the tail assembly. The other end is fastened to a handle that the modeler uses to control the plane's altitude and flight path. When the hobbyist tilts the handle up, one wire raises the elevator, pointing the nose of the plane upward. Tilting the handle down causes the other wire to lower the elevator and point the plane's nose downward.

Some control-line models have only one line, which both raises and lowers the elevator. Others have a third line that controls the engine power and thus the speed of the plane. Jet-powered control-line models have flown nearly 250 miles (400 kilometers) per hour.

Radio control models are controlled by means of a transmitter that sends radio signals to the airplane. The model carries a tiny radio receiver that decodes the signals and passes the information to electric motor devices called *servos.* The servos move control surfaces on the wings and tail assembly, enabling the model to rise, sink, or turn. Servos also control the speed of the plane's engine, lift and lower the landing gear, and open hatches from which parachutes can be dropped.

Some radio control gliders rank among the largest model airplanes. Their wings measure from 9 to 16 feet (3 to 4.9 meters) long. These long wings enable the plane to stay aloft for extended periods when steered into rising air currents. Radio control is also used to pilot model helicopters and racing and acrobatic model aircraft. John Worth

AP/Wide World

A major airport, such as Los Angeles International, *shown here,* may handle more than 200 takeoffs and landings per hour at peak times. Thousands of passengers pass through the airport daily.

Airport

Airport is a place where airplanes and other aircraft take off and land, and load and unload passengers and cargo. Air travel has become the chief means of long-distance transportation, and modern aircraft provide the safest means of travel. Every day, the world's airports handle millions of passengers flying on thousands of commercial airplanes for business and leisure travel.

Airports are exciting places to see commercial airliners, general aviation aircraft, and sometimes even military aircraft. Overhead, planes approach or depart. On the ground, one plane after another takes off or lands. Automobiles, buses, taxis, and even trains carry travelers to and from the passenger terminal. Thousands of people fill the terminal area. Most of them are passengers. Others are employees of the airport, airlines, or commercial establishments operating in the airport.

The largest airports resemble small cities. Many have hotels, restaurants, banks, post offices, and shops, as well as their own police force, fire departments, medical facilities, and utility plants and facilities. These services and facilities are important and useful for passengers and employees at an airport. In addition, some of them help produce the income necessary for the airport to operate successfully. During lengthy flight delays or emergencies, these services can become vital.

Airports differ from other transportation terminals, such as bus or train stations, in two important ways: (1) airports require more land, and (2) most airports are far from the centers of the cities they serve. An airport needs much more land to accommodate the same number of passengers as a bus or train station. A medium-sized city airport needs from 700 to 3,000 acres (280 to 1,200 hectares). The largest airport in the world in area—King Khalid International Airport near Riyadh, Saudi Arabia—covers 55,510 acres (22,464 hectares). The largest airport in the United States, Denver International Airport, has an area of approximately 34,000 acres (14,000 hectares).

National governments, state-sponsored bodies, local governments, and corporations own most of the world's large airports. Many small airports are privately owned.

In most countries, one or more federal agencies oversee airport certification, air safety, pilot qualifications, and the certification and inspection of aircraft. In the United States, for example, those agencies are the Transportation Security Administration (TSA) and the Federal Aviation Administration (FAA). In Canada, the agency is the Ministry of Transport; in India, the Ministry of Civil Aviation; and in the United Kingdom, the Civil Aviation Authority. More than 160 countries, including Australia, Canada, India, South Africa, the United Kingdom, and the United States, belong to the International Civil Aviation Organization (ICAO) of the United

Paul P. Bollinger, Jr., the contributor of this article, is Vice President of Aviation Client Services for HNTB Corporation, a consulting firm that plans and designs airports and other facilities.

Nations. The ICAO establishes standards for its members in such areas as airport safety, operations, and air traffic control.

In addition to licensing U.S. aircraft and pilots and certifying airports and airlines, the FAA regulates safety and sets design and operations standards for airports. The FAA also operates air navigational aids and controls air traffic. The TSA, an organization within the U.S. Department of Transportation, is responsible for airport and airline security in the United States.

Kinds of airports

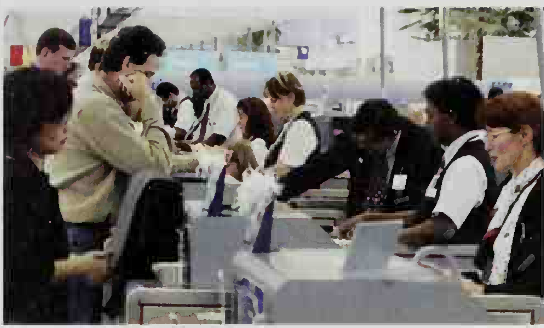
Airports are classified in different ways in different countries. The FAA classifies United States civilian airports as either *commercial service airports* or *general aviation airports*. Military airfields make up a third classification.

Commercial service airports, also called *air carrier airports,* serve planes of commercial airlines. They may also serve such small aircraft as business, charter, or private planes. Nearly all major civilian airports are commercial service airports.

A commercial service airport may serve regional, national, or major airlines—or a combination of these types. *Regional airlines* generally fly short routes using smaller aircraft and connect small communities with one or two large airports. However, some regional jets fly routes of up to 1,000 miles (1,600 kilometers). *National airlines* fly from large airports as well as smaller ones, and they use both large and small jet aircraft. *Major airlines* are large air carriers that generate annual revenues of more than $1 billion in U.S. dollars. They generally provide both national and international flights.

Most airports that handle international flights have the word *international* in their names. International airports serve airlines of both their own country and other countries.

General aviation airports serve all types of aircraft except *scheduled airliners*—planes that operate over specified routes on a timetable. They serve business, charter, and private aircraft as well as scheduled air taxis, which carry passengers between towns and to and from commercial service airports. In addition, general aviation airports handle small aircraft used for aerial surveys, crop-dusting, and flight instruction. Airports that handle only specialized aircraft, such as helicopters or seaplanes, also fall into this category.



There are thousands of general aviation airports ranging from small grass or gravel strips to large, busy airports that handle huge corporate jets. The FAA classifies all general aviation airports—except those that serve only specialized aircraft—in four groups. The classifications are based on the size of the planes the airports can handle. *Basic utility airports* serve single-engine and some small twin-engine, propeller-driven planes. *General utility airports* can handle slightly heavier propeller aircraft. *Basic transport airports* can accommodate small jet airplanes. *General transport airports* handle all types of aircraft.

Special classifications of general aviation airports include *heliports* and *seaplane bases*. Heliports are areas where helicopters land and take off. A heliport may be on the ground, the roof of a building, or the deck of a ship. Seaplane bases are used by seaplanes and *amphibians,* aircraft that can land and take off on water or land. Seaplane bases may be on bays, lakes, or rivers. Most seaplane bases have onshore facilities to service the aircraft. The world's busiest seaplane base is in Anchorage, Alaska.

Military airfields are airports operated by the armed forces. Some military units, such as the U.S. Air National Guard, share facilities at commercial airports. Military airfields range in size from small fields for light planes to huge airports for heavy jet bombers.

Airport facilities

An airport's facilities depend on the size of the community it serves, the area of land it covers, and the type

Air traffic controllers directing aircraft movements

An overview of an airport

Airports provide facilities for aircraft and their crews, passengers, and cargo. The airport diagramed below is designed on the satellite plan. In this plan, departing passengers enter the main terminal, then go to separate terminals called *satellite terminals* to board their planes.The control tower is a navigation center from which air traffic controllers direct aircraft movements. The airport also has hangars in which aircraft are stored and repaired, runways where the planes take off and land, and cargo areas.

of air service it provides. This section deals chiefly with the numerous facilities provided by most large commercial service airports. The subsection *Planning and building an airport* later in this article discusses different types of designs for airport passenger terminals.

The passenger terminal. Passengers begin and end their flights at the passenger terminal. Airports may have one or more terminal buildings. At airline ticket counters, departing passengers purchase tickets, have their tickets checked, and receive boarding passes. They also can leave their baggage to be loaded into the airplane's cargo hold. Loudspeakers, flight monitors, and electronic message boards announce flight arrivals and departures. Boarding lounges provide seats for waiting travelers and airline crews.

Passengers board and leave aircraft from openings called *gates.* At most large airports, an enclosed walkway called a *boarding bridge*—or, under a common trade name, a *Jetway*—connects the terminal gate with the aircraft during boarding. Arriving passengers pick up their luggage at a baggage claim area in the passenger terminal.

Many of the activities in the passenger terminal take place behind the walls or under the floor. These activities include the transport of baggage and cargo from the ticket counter to the aircraft. In addition, airlines maintain offices in these areas.

Each airline has a *briefing room,* where pilots receive flight information. The briefing room includes a *dispatch office,* which handles communications with the airline's

WORLD BOOK diagrams by Einbecker-Butler & Associates

The terminal area of many airports has three main levels that handle a variety of activities. An additional underground level may provide links with mass transportation and intra-airport trains.

operations center and with its airplanes, both on the ground and in flight. The airport manager and the management staff, who oversee the operation of the airport, also have offices at the airport.

Hangars are buildings in which aircraft are stored and repaired. Most airlines have their own hangars. Some hangars can hold several large jets at one time. Most airports locate hangars far enough from the terminal building to avoid interference with aircraft traffic on the ground.

The control tower is the air traffic nerve center. In the tower, air traffic controllers use radar, radio, signal lights, and other equipment to direct air traffic near the airport as well as movements of aircraft on the ground. Control towers at the busiest airports may handle more than 200 landings and take-offs an hour during peak periods. Large, tinted windows enable controllers to see all the aircraft in motion at the airport. Some control towers are over 200 feet (60 meters) tall.

Runways must be long enough and wide enough to handle the largest planes using the airport. They must be as level as possible. However, runways slope slightly from the center toward each side to provide good drainage. A government body usually sets minimum runway lengths for different types of aircraft. Many small airports use only strips of mowed grass called *landing strips.* Some of these strips are only 2,000 to 2,500 feet (610 to 760 meters) long. The runways of large airports are paved with concrete or asphalt. These runways may be as long as 13,000 to 14,000 feet (4,000 to 4,300 meters) to handle the biggest planes. Runways must have a *clear zone* at each end to give aircraft additional space to take off or land without endangering people or property on the ground.

Lines painted down the center and sides and across the ends of runways guide pilots in the air and on the ground. Numbers painted on each end of a runway tell pilots the compass direction in which the runway is laid out. For example, the numbers 18 and 36 indicate a north-south runway. The number 18 (an abbreviation for 180°) is painted on the north end of the runway, and the number 36 (360°) appears on the south end. Most airports design runways in at least two directions so planes can take off and land as nearly as possible into the wind.

At night and other periods of low visibility, white lights outline each runway, and green lights mark the beginning of a runway. Red and white approach lights shine just in front of the area where a plane should touch down.

Loading aprons and taxiways. The aircraft parking area at the gates of the passenger terminal is called a *loading apron* or *tarmac.* Although the word *tarmac* originally referred to a paving material made of crushed rock and tar, the apron is actually made of concrete or asphalt because these materials better resist damage from heat and fuel leaks. While an airplane is on the apron, workers refuel it and load baggage, cargo, and meals for the passengers. The crew and passengers board airplanes on the loading apron. A small airport may service only 1 or 2 aircraft on the apron at one time. Large airports may accommodate more than 100 planes at once.

Aircraft use lanes called *taxiways* to taxi from the apron to the runways and from the runways to the hangars. Many large airports have double taxiways so aircraft can move to and from the runways and hangars at the same time. At night, the taxiways are marked with blue lights. Red lights are used to mark any barriers or other dangers.

Ground transportation and parking. Large airports provide roadways alongside the terminal buildings where airport buses, hotel vans, private automobiles, limousines, and taxis can pick up and drop off passengers. Some airports are connected to the city center by light rail systems or subways.

All airports maintain parking facilities. Most large airports have multistory parking garages, which take less land than parking lots do to hold the same number of cars. Parking provides a major source of revenue for many airports.

Airport operations

The airport manager and the management staff direct the maintenance, operation, and safety of the entire airport. In some regions, they may be responsible for several airports. The management staff at a large airport is divided into several departments, such as administra-

Airborne Express

Cargo handling is a major airport activity. Many airlines have special cargo planes like the one above. Workers pack small cargo items in containers shaped to fit the airplane's interior. They load the cargo through the plane's wide door.

WORLD BOOK photo

Refueling is one of the important activities carried out while a plane stands outside the terminal between flights.

tion, finance, operations, maintenance, planning, engineering, safety, security, and public affairs. The airport staff works to ensure that the airport operates safely and efficiently. Every day, the staff checks the safety of the airport's terminal, taxiways and runways, parking areas, and roadways.

An airport must operate like a business. Airports rent space to the airlines for offices, check-in counters, and baggage areas. In addition, airports give leases to restaurants, gift shops, hotels, and car rental agencies. The leases provide revenue to pay for the operation and development of the airport. In addition, the airport receives income from parking lots, telephones and advertisements in the terminal, and landing fees paid by the airlines. Most commercial service airports also get income from a *passenger facility charge,* a small fee assessed on each passenger's ticket.

Airline passenger services. Airline workers provide many services for passengers at commercial airports. Ticket counter employees sell tickets, check in passengers who already have tickets, and provide information about the times and gates for flight arrivals and departures. A passenger's ticket may be a printed ticket or an *e-ticket,* a ticket purchased over the telephone or the Internet and recorded electronically with the airline. Ticket counter agents use airline computer systems to quickly print boarding passes and baggage tags. Ticket kiosks at some airports enable passengers to check themselves in without the aid of a ticket agent.

Ticket counter workers also check in passengers' baggage. Baggage handlers and *ramp agents* (workers that service aircraft between flights) see that baggage is loaded on the correct flights. After a plane reaches its destination, handlers unload bags and transport them to the baggage claim area.

Other airline workers include an airline station manager, who oversees passenger services, and reservations agents, who keep records of flight reservations. The dispatch staff maintains contact with planes in the air and with other airports that the airline serves.

Cargo handling. Most airports use the term *cargo* for mail and all other freight carried by aircraft except baggage. Much air cargo includes items that spoil rapidly, such as flowers, fruits, vegetables, seafood, and medical supplies, including organs for transplant. Other typical air cargo includes such products as electronic products and machinery parts. Both cargo aircraft and passenger aircraft carry cargo.

Large airports have several separate terminals for cargo processing. Cargo brought in from the surrounding area is often sorted at the airport for various flights. Postal workers sort any mail. Carts, towed by small vehicles called *tugs,* then carry the cargo to the apron, where workers load it into passenger or cargo aircraft.

Small aircraft services. Commercial service airports must provide many services for small planes that are not operated by commercial airlines. In the United States, these small planes account for about 10 percent of the traffic at most large commercial service airports and approximately 65 percent of the flights at small commercial service airports. A Fixed Base Operator provides these small aircraft with such services as fuel, hangars, mechanical maintenance, ground transportation, and food.

Air traffic control. In the control tower, the air traffic controllers guide aircraft as they land, take off, and taxi. The controllers see that the traffic keeps moving smoothly, rapidly, and safely. They must have good eyesight, speak clearly over the radio, and think quickly. The controllers must also remain calm during periods of heavy air traffic. Their job becomes especially difficult when fog or other weather conditions reduce visibility. In such situations, the controllers must rely entirely on radar to locate and guide aircraft in flight.

Planes approach or depart on assigned routes called *traffic patterns.* Instruments in aircraft cockpits electronically display an airport's traffic patterns for pilots to follow. When necessary, a pilot can safely fly without instruments if the weather is clear enough to see other aircraft and the airport.

The control tower has several types of electronic all-

Airport terms

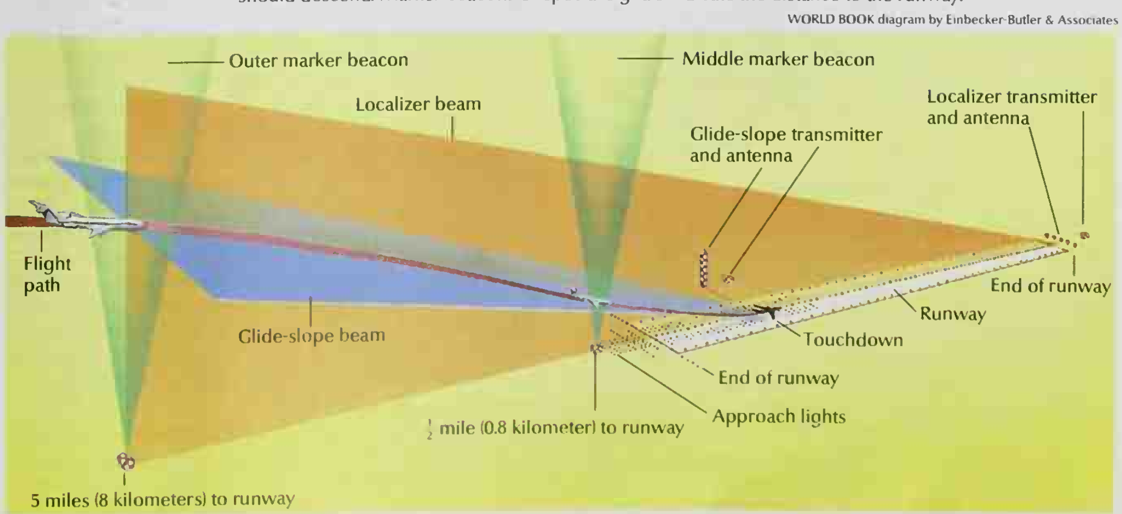
Air carrier airport is an airport that serves planes of commercial airlines. Air carrier airports may also serve other types of aircraft, such as business, charter, or private planes.
Cargo is all freight, except baggage, carried by an airplane.
Closed in means an airport is closed to air traffic because of bad weather.
Control tower is a glass-enclosed booth equipped with radar, radio, lights, and other navigation aids for directing aircraft movements on the ground and in the air. *Air traffic controllers* work in the tower or in buildings called *air route traffic control centers.*
Gate is the airport terminal entryway passengers use when boarding or leaving planes. Each airliner is assigned a *gate position* for loading or unloading passengers.
General aviation airport is an airport that does not serve scheduled airlines. General aviation airports serve mostly air taxis and business, charter, and private planes.
General aviation traffic is all air traffic except scheduled airline flights.
Loading apron is the paved area around the terminal where aircraft are serviced, passengers board and leave planes, and baggage and cargo are loaded and unloaded.
Taxiway is a paved lane aircraft use to move between the apron, hangars, and runways. Aircraft follow a *taxi route* to reach a take-off point or parking area.
Terminal is the main airport building for passenger services. It also houses offices of airline employees and the airport management staff.

weather landing equipment to help bring planes down safely. Most commercial airports have an electronic aid called an Instrument Landing System (ILS). The ILS sends radio signals to receivers on an airplane. The airplane receivers show the pilot whether the plane is to the left, right, above, below, or directly on the correct approach path to the airport.

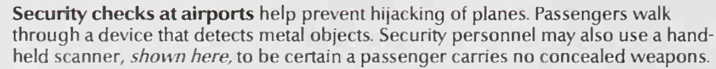
Other navigation aids include Airport Surveillance Radar (ASR), the Microwave Landing System (MLS), and the Global Positioning System (GPS). The ASR gives traffic controllers a view of all aircraft activity within about 50 miles (80 kilometers) of the airport. This information helps controllers prevent midair collisions by choosing the safest route for pilots to follow.

The MLS is a precision landing aid similar to the ILS. The MLS provides additional information to help the pilot select the most appropriate approach path for each type of aircraft. Pilots of helicopters and small aircraft are thus able to select shorter and steeper approaches to the runway than those selected by pilots of larger aircraft.

The GPS uses a network of navigation satellites to enable pilots anywhere on earth to determine their location. These satellites send out radio signals that are picked up by receivers on the aircraft. GPS equipment can compute an aircraft's position, speed, and time every second. The system bases the calculations on the distances between the satellites and the receiver. See Global Positioning System.



Airport security. Commercial service airports worldwide maintain a high level of security to prevent such dangerous activity as terrorist hijackings and bombings. TSA personnel search airplanes for hidden weapons and explosives. They also inspect passengers' baggage before it goes onto the plane. Passengers must pass through electronic scanners that detect guns, knives, and other metal objects.



The federal government has established security regulations for all air carrier airports in the United States. The regulations include rules on inspection of planes, baggage, and passengers. The airports are required to have law enforcement personnel on the premises as part of their security programs. Federal legislation passed after terrorist attacks in the United States in September 2001 set deadlines for increased security measures at airports. These measures include screening all checked baggage for explosives. The new law also transferred responsibility for passenger and baggage screening from personnel employed by private security firms to federal employees.

Other operations. Some airline and privately contracted employees work in the hangars. There, trained

Making instrument landings The *Instrument Landing System* (ILS) sends radio signals to receivers on a plane. A vertical *localizer beam* guides the plane to the runway. A *glide-slope beam* shows the angle on which the plane should descend. *Marker beacons* or special signals indicate the distance to the runway.

Security checks at airports help prevent hijacking of planes. Passengers walk through a device that detects metal objects. Security personnel may also use a hand-held scanner, *shown here,* to be certain a passenger carries no concealed weapons.

United Airlines

An airline mechanic works to keep aircraft in safe flying condition. Mechanics perform routine checks and make needed repairs.

mechanics repair planes and other employees keep records of spare parts needed for urgent repairs. Many airline employees work in the apron area. Some direct aircraft into parking spaces. Mechanics check the engines and other equipment. Some employees clean the interior of airplanes between flights. After all the work has been completed, the captain of an aircraft notifies the dispatch office that the flight is ready to leave.

Airlines contract with commercial flight kitchens to prepare food for passengers on some flights. Dietitians plan the menus, chefs do the cooking, and food handlers transport the meals to waiting aircraft.

At most U.S. airports, FAA employees operate the control tower and maintain electronic equipment in the tower. The workers who do passenger and baggage inspection in U.S. airports are also federal employees. Other federal workers at airports include postal workers, Customs Service and Immigration Service personnel, and security personnel.

Many large commercial service airports have a station for their national weather service. Airports and airlines typically use private weather services to check conditions in specific areas of interest. Such services provide airlines, pilots, and airport operators with world and national weather information.

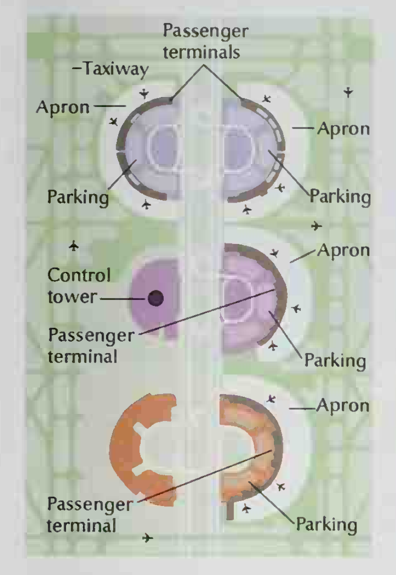
Airport development

Planning and building an airport takes a long time because of the environmental and economic issues that must be considered. When a governmental body wishes to build an airport, it may take several years and many studies before construction can begin. The first step is to hire an airport planning firm to select the best site for the new airport. The planners evaluate each potential site for many factors, including environmental impact, distance to the city, homes and businesses that must be moved, and difficulty of building on the terrain. The governmental body then holds public hearings where elected officials and the public can express their opinions about the site that has been chosen.

Following approval by the community and the federal government, funding for the airport must be arranged. Voters may be asked to approve a bond issue to help pay for the new facility. The governmental body then contracts with an architectural firm, an engineering firm, contractors and suppliers, and perhaps a project management firm to design and build the airport. The actual construction of a major airport usually takes three to five years.

Few cities build new airports. Instead, most cities expand or renovate their existing airports. Planners prepare a document called an *airport master plan.* The plan shows the airport's present facilities and describes how the airport should be developed to meet future needs. These plans generally show the location of new runways and terminal buildings so these areas can be protected for future development. The nation's government often funds such plans.

As cities allow homes and businesses to be built near an airport, they decrease the ability of the airport to grow in the future. Airports, airlines, the federal government, and local communities must all work together to ensure that airports operate safely and efficiently.

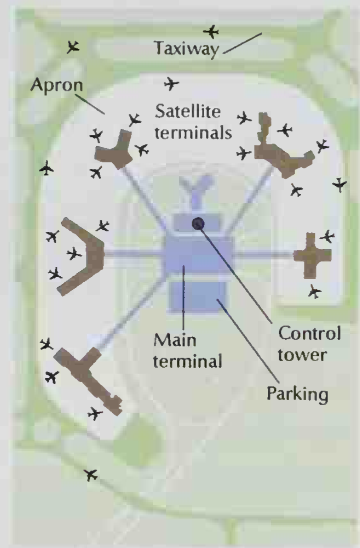


Terminal designs. Designs for airport passenger terminals use one of three types of plans. These plans are: (1) linear, (2) pier, and (3) satellite.

In a linear plan, arriving and departing passengers enter and exit the terminal at various points along the building's curb. Aircraft also park along the length of the building. This arrangement results in short walking distances for passengers. Linear plans work best for passengers beginning or ending their trips. Such plans are less efficient, however, for passengers or baggage transferring between flights.

A pier plan has a central terminal building with a pier or passageway called a *concourse* that extends onto the apron where the airplanes park. Although this type of plan may create longer walking distances, it allows

Types of airport passenger terminals



Common terminal designs include linear, pier, and satellite plans. In a *linear plan,* passengers arrive at points along the length of the building, and the planes park along the other side. A *pier plan* has a central terminal with piers that extend onto the apron where the aircraft park. In a *satellite plan,* people board and leave planes from separate satellite terminals.

Linear plan

Pier plan

WORLD BOOK diagrams by Russ Coombs, Steven Edsey and Sons

Satellite plan

more aircraft to park near the building. It also centralizes such functions as baggage handling, ticketing, and check-in. Many modern pier terminals have moving sidewalks to help passengers who have to walk long distances.

In a satellite plan, passengers board aircraft from terminals called *satellite terminals.* Passengers travel from the main terminal to a satellite terminal by riding a shuttle or a driverless electric rail car called a *people mover.* Shuttles and people movers run at ground level, overhead, or underground from the main terminal. The satellite plan enables a greater number of aircraft to park at a terminal and shortens walking distances.

Airport noise. When airports were built years ago, they lay far from cities and people's homes. However, as cities have grown, more people have come to live near airports. As a result, aircraft noise has become an increasing problem. In the United States, federal noise laws have resulted in airlines phasing out old, noisy aircraft and purchasing quieter new planes, or replacing engine parts on existing aircraft. In addition, airports sometimes obtain federal funds to buy homes affected by noise or to pay for the soundproofing of schools, libraries, and homes. At many airports, pilots must follow specific approach and departure patterns to reduce the impact of noise on populated areas.

What is the job of the airport management staff?
What are some of the navigation aids used by air traffic controllers?
What are some major sources of revenue at commercial airports?
What are some of the responsibilities of the FAA?
What is the largest airport in the world? In the United States?

Culver

During the 1920's and 1930's, the United States Navy airship *Los Angeles, shown here,* performed such military tasks as escorting ships and patrolling coastal waters.

Goodyear

Today's airships are often used for commercial purposes. The Goodyear Tire & Rubber Company operates several blimps, which serve mainly as advertising or public relations craft.

Airship is a lighter-than-air aircraft with an engine that moves it through the air. Airships also normally have equipment for steering. The main body of a typical airship is a huge, cigar-shaped balloon filled with a lighter-than-air gas. The gas raises the craft and keeps it aloft.

An airship differs from a *free-floating balloon,* which is neither powered nor steered. Airships also differ from helicopters and airplanes, which are heavier than air. Helicopters and airplanes use their engines and blades or wings to lift them and keep them aloft.

Airships were introduced in the 1800's as the first flying machines capable of prolonged flight and of being steered. This feature led to the craft being called *dirigibles,* which comes from the Latin word *dirigere,* meaning *to direct.* In World War I (1914-1918), airships were used as bombers, for protecting ships against submarine attack, and for other duties. Before and after the war, they were used to carry passengers. Airship passenger services reached their height in the 1930's, but a series of disastrous crashes and the increasing popularity and long-range capability of the airplane brought airship passenger services to an end. Today, several countries have shown a renewed interest in airships for advertising, cargo operations, passenger transport, recreational flying, and surveillance.

Types of airships

There are three main types of airships: (1) nonrigid airships, (2) rigid airships, and (3) semirigid airships.

Nonrigid airships were the first airships and are the most popular type today. They have no major internal structures and no outer framework. Gas pressure causes the outer skin, called the *envelope,* to keep its shape. Modern envelopes are made of synthetic materials.

The smallest airships have been nonrigid craft. Some have measured less than 75 feet (23 meters) long. The largest nonrigid airships were the United States Navy's ZPG-3W airships. These craft were flown from 1958 to 1962 and were used for airborne early-warning duties. Each ZPG-3W measured about 403 feet (123 meters) long. Today's nonrigid airships average about 150 feet 46 meters) in length. They cruise at approximately 35 to 40 miles (56 to 65 kilometers) per hour at heights reaching about 10,000 feet (3,050 meters).

The U.S. Navy's B-class nonrigid airships, built in 1917, gave rise to the term *blimp* for nonrigid craft. The term came from *B-nonrigid,* or *B-limp.*

Rigid airships, the largest airships, have a greater carrying capacity than nonrigid craft. But few are flown today. The main body of a rigid airship is called the *hull.* Most early rigid craft had a hull consisting of a wooden or metal framework that supported the outer skin. Today, composite materials can be used. The most famous rigid airships were called *zeppelins,* after Count Ferdinand von Zeppelin, a German airship pioneer.

Zeppelins were cigar-shaped and ranged from about 400 feet (120 meters) to over 800 feet (240 meters) long. Advanced models could reach speeds of about 80 miles (130 kilometers) per hour. Inside the hulls were several compartments, called *gas cells,* that held the lifting gas. Many hulls contained corridors along which cargo, crew quarters, and the fuel tanks were located

Semirigid airships became fairly common in the early 1900's. They often resembled nonrigid ships, except that a support ran along most of the length of the envelope and helped maintain its shape and distribute loads. Semirigid airships were often larger than nonrigid craft. A few semirigid craft are being developed and flown today, but they are far less common than nonrigid craft.

How airships fly

Lift is the force that raises an airship off the ground and keeps it aloft. Airships generate lift because the gas they contain has a lower density than the air outside the craft. Airships hold enough of this lighter-than-air gas to overcome their own weight and rise from the ground.

Early airships contained hydrogen, the lightest of all gases. But hydrogen is highly flammable, which was an important factor in a number of airship disasters. As a result, helium replaced hydrogen for use in airships.

Thrust is the force that moves an airship through the air. Most airships use engines and propellers to obtain

thrust. On large rigid airships of the early 1900's, the engines and propellers were in *gondolas* (cars) attached to the hull. Such craft had separate gondolas for the passengers and crew. On most nonrigid and semirigid airships, engines are mounted on a gondola that also holds the crew and passengers.

Control. Most airships have tail structures that include *fins, rudders,* and *elevators.* Fins are large, fixed surfaces. Typically, four fins are set equally distant from one another around the ship's *stern* (rear). The smaller, movable rudders and elevators are surfaces attached to the fins. A pilot moves the rudders to steer and the elevators to raise or lower the ship's nose.

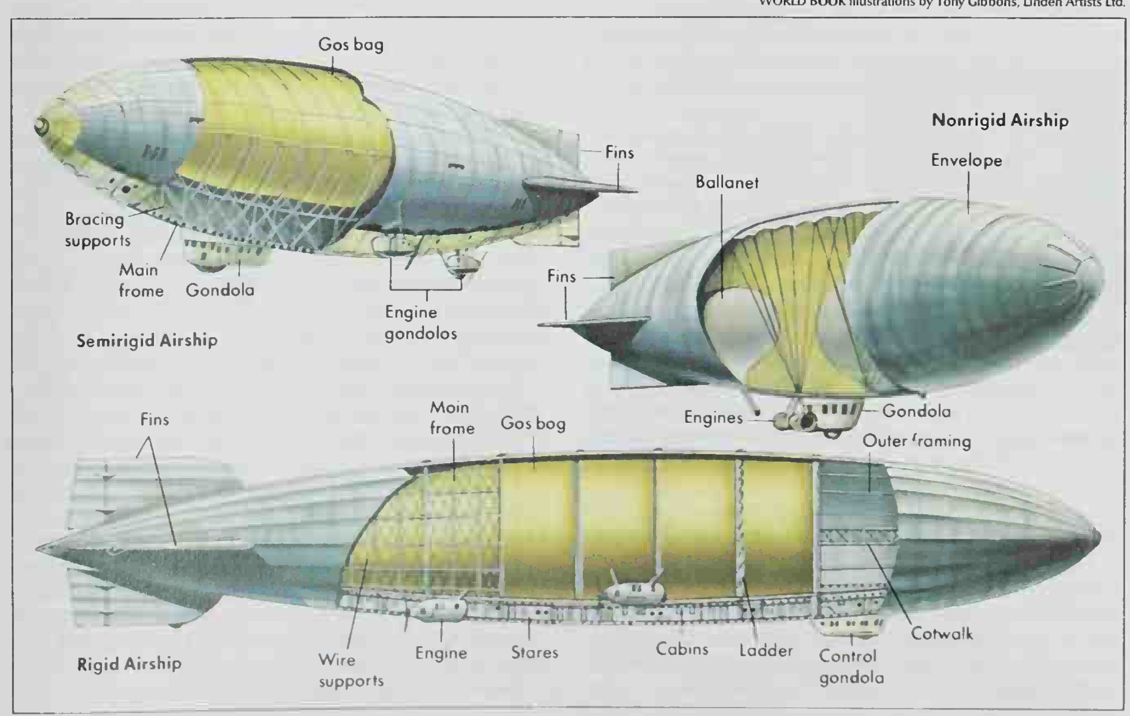
For improved control, many early airships carried weight called *ballast,* usually water. If rain or other weather conditions made the craft heavier in flight, the pilot could release ballast to lighten the craft and thus maintain altitude. Some modern airships carry ballast.

Ballonets are air-filled bags or compartments inside the envelope of nonrigid and semirigid craft. Ballonets help maintain the shape of the envelope. If gas pressure in the envelope decreases, air is pumped into the ballonets so that the envelope will not sag. Ballonets can also be used to stiffen the envelope of a rigid airship.

Storage. Early airships were kept in huge hangars or sheds, but moving the craft in and out of these shelters sometimes proved disastrous. Engineers partly solved the problem when they developed the *mooring mast,* a high, stable tower to which an airship could be anchored without touching the ground. The bow of the airship was secured to the tower. Mooring masts allowed airships a limited amount of movement to help them survive high winds. To enter rigid craft, the crew and passengers passed up a staircase within the mast.

Low mooring masts were developed to secure nonrigid airships close to the ground. The crew and passengers can board these craft directly into the gondola. Some modern airships do not require masts at all.

History



The first airships evolved from balloons. Henri Giffard, a French engineer, built and piloted the first powered airship. As with many balloons, ropes covered the envelope and hung down to support an open gondola. But unlike the ball-shaped balloons, Giffard's airship was cigar-shaped, and the gondola supported a 3-horsepower (2.2-kilowatt) steam engine. A saillike rudder was carried in the gondola.

On Sept. 24, 1852, Giffard flew his craft about 17 miles (27 kilometers) from Paris to Trappes, near Versailles, at an average speed of 5 miles (8 kilometers) per hour. The small rudder and engine enabled him to alter his course, but the craft was not properly steerable.

In 1884, Charles Renard and Arthur Krebs, two French inventors, completed *La France.* This airship had a battery-powered electric motor that produced about 9 horsepower (7 kilowatts). It also had an efficient rudder and elevator. Renard and Krebs flew *La France* around a 5-mile (8-kilometer) circular course near Paris at speeds over 14 miles (23 kilometers) per hour. In 1901, the Brazilian-born inventor Alberto Santos-Dumont completed a controlled journey around the Eiffel Tower in

Kinds of airships There are three main types of airships. A *nonrigid airship* has no framework supporting its gas-filled *envelope* (outer skin). In a *semirigid airship,* supports brace the craft's gas-filled bag. An extensive inner framework, usually of wood or metal, supports the gas bags of a *rigid airship.*

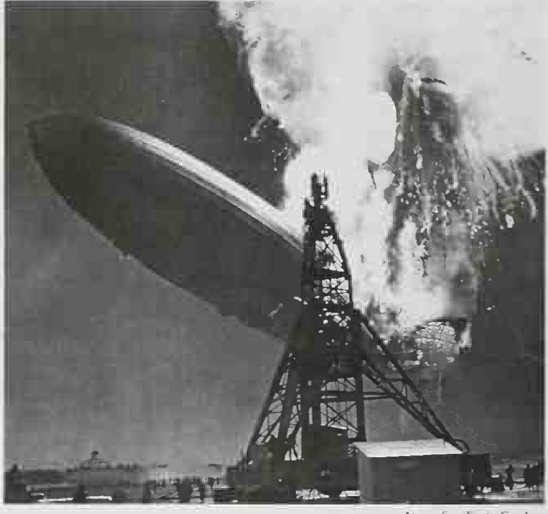
WORLD BOOK illustrations by Tony Gibbons, Linden Artists Ltd.

Paris. His adventures won him great popularity.

David Schwarz of Austria designed the first truly rigid airship. His craft flew on Nov. 3, 1897. But due to windy conditions, mechanical problems, and an inexperienced pilot, the craft crashed.

The zeppelins. In 1900, Count Ferdinand von Zeppelin flew his first airship, the LZ-1. It was 420 feet (128 meters) long and could reach a top speed of about 17 miles (27 kilometers) per hour. It made only three flights because it was underpowered and lacked proper control. Zeppelin completed the LZ-2 in 1905, and he launched the LZ-3 in 1906. The German Army later made the LZ-3 the first military zeppelin.

In 1909, Zeppelin helped establish the world's first commercial airline, known as DELAG. The *Deutschland,* DELAG's first airship, was over 485 feet (148 meters) long and had three 120-horsepower (90-kilowatt) engines. From 1910 to 1913, over 34,000 passengers flew by zeppelin airships on DELAG flights.



World War I. During World War I, Germany used zeppelins and other airships to patrol the North Sea and scout enemy craft and positions. Germany was also the only country to make major use of rigid airships for strategic bombing. But the frequent raids over England caused little damage. The largest user of rigid airships during the war was the German Naval Airship Division. It received about 70 zeppelin and Schütte-Lanz craft. Due to accidents, bad weather, and enemy fire, 53 of these airships were lost. The capabilities of zeppelins improved dramatically. For example, the L-59 once flew 4,200 miles (6,800 kilometers) nonstop. Its five engines could produce speeds of over 60 miles (95 kilometers) per hour.

The United Kingdom built and operated a large number of nonrigid airships during the war. British airships primarily protected ships from submarine attack. The United States used nonrigid airships for some overwater patrol duties and antisubmarine warfare. Other countries that used airships during the war included France and Italy.

Between world wars. After World War I, airships became bigger, faster, and stronger. For example, in 1919, the United Kingdom's rigid R-34 made the first transatlantic crossing by an airship. In 1926, the Italian-built semirigid *Norge* became the first airship to fly over the North Pole. The replacement of hydrogen with helium to prevent airship disasters began in the 1920's, on U.S. craft.

In the 1920's and 1930's, the U.S. Navy experimented with giant rigid airships. The *Akron,* launched in 1931, and the *Macon,* launched in 1933, carried fighter airplanes. While in flight, these airships could launch and receive the planes. In April 1933, the *Akron* went down in a storm off the coast of New Jersey, killing 73 people. In February 1935, bad weather forced the *Macon* into the sea off the coast of California, killing two people and ending U.S. construction of rigid airships.

The most successful rigid airship ever built was the German LZ-127 *Graf Zeppelin.* Between 1928 and 1937, the *Graf Zeppelin* flew more than 1 million miles (1.6 million kilometers) and carried over 13,000 passengers, many of them overseas. In August 1929, it made the first airship flight around the world. The *Graf Zeppelin* ranks among the fastest rigid airships ever flown.

News Syndicate Co., Inc.

The ***Hindenburg*** explosion marked the end of regular passenger service on airships. In 1937, this German airship, one of the largest ever built, burst into flames while approaching its dock in Lakehurst, New Jersey. The ship's envelope and hydrogen gas ignited, causing an explosion. Thirty-six people died in the disaster.

The *Hindenburg.* Construction and operation of rigid airships in Germany came to a swift end following the destruction of the *Hindenburg.* One of the largest airships ever built, the *Hindenburg* was about 804 feet (245 meters) long and 135 feet (41 meters) wide. It had a volume of 7,062,100 cubic feet (199,980 cubic meters) and cruised at 78 miles (126 kilometers) per hour. On May 6, 1937, while approaching its docking in Lakehurst, New Jersey, the *Hindenburg* exploded. Of the 97 people on board, 35 were killed. In addition, one member of the ground crew was killed. The ship's envelope material and hydrogen gas had ignited, leading to an explosion. The *Hindenburg* disaster marked the end of the use of airships for regular passenger services. In addition, development of rigid airships ended.

World War II to the present. The evolution of the airplane contributed greatly to the decreased use of the military nonrigid airship during World War II (1939-1945). The U.S. Navy made the only significant use of nonrigid airships during the war, flying mainly its K-class airships. Most of these craft patrolled U.S. coastal waters and escorted surface ships there.

In the late 1950's, the Navy introduced its ZPG-3W nonrigid airships. One ZPG-3W craft crashed at sea in 1960, killing nearly everyone on board. This crash contributed to ending the use of nonrigid airships for military operations.

Today, there has been a significant revival of airships. Most airship companies produce nonrigid craft for commercial and recreational purposes. Some manufacturers also design and build large rigid airships for passenger and heavy cargo operations. Other companies have created hybrid craft that rely on modified wings or other devices to help produce lift in addition to that provided by gas. Michael J. H. Taylor

Ajax the Greater, in Greek mythology, was one of the bravest Greek heroes who fought in the Trojan War. He is called Ajax the Greater to distinguish him from another Greek warrior, called Ajax the Lesser. After the Greek hero Achilles was killed in the war, his armor was unfairly awarded to Odysseus (Ulysses in Latin). Ajax went mad with despair at losing the prize and killed flocks of sheep and cattle that he believed were his enemies. When he regained his sanity, he committed suicide by falling on his sword. A flower is said to have sprung from his blood. Ajax was the son of King Telamon. *Ajax* is the Latin form of the Greek *Aias.* F. Carter Philips

Ajax the Lesser, in Greek mythology, was a great Greek hero during the Trojan War. He is called Ajax the Lesser to distinguish him from another Greek hero of the Trojan War, called Ajax the Greater. Ajax had a sinful character. By raping the Trojan princess Cassandra in the temple of the goddess Athena, he brought divine wrath on the entire Greek force. Athena and the sea god Poseidon destroyed the ships of Ajax and other Greeks in a fierce storm in which Ajax died for his defiance of the gods. *Ajax* is the Latin form of the Greek *Aias.* Ajax was the son of King Oileus. F. Carter Philips

Akbar, *AK bahr* (1542-1605), was the greatest ruler of the Mughal Empire of India. During his 49-year reign, from 1556 until his death on Oct. 27, 1605, he controlled most of north and central India and Afghanistan. He set up the governmental framework of the empire and organized new systems of coinage and taxation.

Akbar had a great interest in all religions and was known for his religious tolerance and his justice. Scholars, priests, and mystics of all religions debated before him. Despite resistance from orthodox Muslims, he won the support of many Hindus, including the Rajputs, who came from a tribal kingdom in northwestern India.

Akbar was born on Nov. 23, 1542, in Umarkot in what is now Pakistan. He was the grandson of Babur, the first Mughal emperor. Akbar became emperor at the age of 13 after the death of his father, Humayun. Patricia Risso

See also **Babur; India** (The Mughal Empire).

Akhenaten, *AH kuh NAH tehn,* ruled ancient Egypt as pharaoh from about 1367 to 1350 B.C. He was married to Queen Nefertiti. Akhenaten was a religious reformer, devoted solely to the worship of Aten, the sun god. During the early part of his reign, perhaps while coregent with his father, Amenhotep III, he abandoned the state religion of Amon. Akhenaten built a new capital at Amarna which he called *Akhetaten,* meaning *horizon of Aten.* Late in his reign, he attacked the old religion and removed the name of the national god Amon from monuments. Akhenaten was also known as a poet and a patron of the arts. Leonard H. Lesko

Akihito, *ah kih HEE toh* (1933-), became emperor of Japan in 1989 upon the death of his father, Hirohito (see **Hirohito**). *Heisei* was chosen as Akihito's reign name, and he is known as the Heisei Emperor.

Akihito was born on Dec. 23, 1933, in Tokyo. After World War II (1939-1945) ended, the life of Japan's imperial family changed. Akihito studied with an American tutor and toured the West. His marriage to a commoner, Michiko Shoda, in 1959 was considered symbolic of Japan's new democracy. The couple had two sons and a daughter. Crown Prince Naruhito, the oldest child, is heir to the throne. Kenneth B. Pyle

Akita is a breed of dog that originated in northern Japan. It was used to hunt bears and other large animals. Akitas were once owned by royalty in Japan, and the dogs are still revered in that country. Akitas are known for their loyalty. They are alert, responsive guard dogs, and they are aggressive toward other dogs.

Akitas are large and powerful, with heavy bones. Males stand from 26 to 28 inches (66 to 71 centimeters) tall at the shoulder. The short coat of the Akita may be

any color, or it may be a mixture of colors.

Critically reviewed by the Akita Club of America

Akiva ben Joseph, *ah KEE vah behn JOH zuhf* (A.D. 50?-135?), was a rabbi who profoundly influenced the development of Jewish law. His name is also spelled Akiba. He emphasized the importance for every Jew of studying the Torah, the first five books of the Bible. Akiva believed that each word and letter of the Bible was significant. He sought lessons from the spelling itself as well as from the wording of the text. He collected and explained legal traditions along with interpretations of the Bible. This work became the basis of the Mishnah, the fundamental code of Jewish law. Akiva was known for his modesty, optimism, concern for the poor, and love of Israel. He is the subject of many stories in Jewish literature.

Akiva was born in Judea in central Palestine. After the Roman rulers of Judea issued decrees forbidding the practice of Judaism, Akiva went to Rome on behalf of the Jewish community. However, the Romans did not relent. In 132, the Jews revolted under the leadership of the warrior Bar Kokhba. The Romans crushed the revolt in 135. They arrested Akiva and executed him for practicing his religion. Lawrence H. Schiffman

Akkad. See Sargon of Akkad.

Akron (pop. 217,074; met. area pop. 694,960) is a city in northeastern Ohio. It lies on the Cuyahoga and Little Cuyahoga rivers. For the city's location, see Ohio (political map).

Akron was once the world's largest producer of tires, and it was known as the *Rubber Capital of the World.* Today, the city is a center for the research and development of rubber products. The Goodyear Tire & Rubber Company—the largest rubber company in the United States—has its main office in Akron.

The city. Downtown Akron includes a federal courthouse and state government offices. A sports stadium is also located in the downtown area. A restaurant and entertainment district has developed around the stadium. A few blocks from the stadium is Inventure Place, the home of the National Inventors Hall of Fame.

The Loral Airdock, the building where Goodyear once built blimps, is a well-known feature of the Akron skyline. It stands more than 20 stories tall and covers 364,000 square feet (33,800 square meters) of floor space. It is one of the world's largest buildings without interior supports.

Akron's cultural attractions include the Akron Art Museum, which specializes in modern art, and the Akron Civic Theatre, built in 1929. Stan Hywet Hall, a mansion built by Goodyear founder F. A. Seiberling, is now used for cultural events. The Akron Symphony Orchestra and the Ohio Ballet perform at E. J. Thomas Performing Arts Hall. Blossom Music Center, north of the city in Cuyahoga Falls, is the summer home of the Cleveland Orchestra and hosts other musical performances. Akron is host each year to the All-American Soap Box Derby (see **Soap Box Derby**).

The University of Akron is in downtown Akron. Kent State University is northeast of Akron in Kent. The Northeast Ohio Universities College of Medicine is to the east of Akron in Rootstown.

Economy. Akron is a center for the research and development of rubber products. Service industries, such as health care and retail trade, are also important in Akron. The city has several hospitals and serves as a medical center for the region. It is also an important trucking center.

Akron-Canton Regional Airport and Akron-Fulton Municipal Airport serve the city. Passenger trains and freight trains also serve Akron.

Government. Akron has a mayor-council form of government. The voters elect the mayor to a four-year term. They also elect 13 council members. Ten of the members, representing different sections of the city, serve for two years. Three of the members represent the entire city and serve for four years. Akron is the seat of Summit County.

History. Chippewa, Delaware, Erie, and several other groups of Indians lived in what is now the Akron area. In 1825, General Simon Perkins, a banker, developer, and land agent, and settler Paul Williams founded Akron on a ridge that rises 950 feet (290 meters) above sea level. The settlement was named after the Greek word *akros,* meaning *high point.* Akron became a thriving trade center after the completion of the Ohio and Erie Canal in 1832 and the Pennsylvania and Ohio Canal in 1840. The canals opened the way for trade with cities in the eastern United States. Akron was incorporated in 1865.

In the 1800's, Akron was a center for the production of cereal, clay pipe, and farm equipment, but it was rubber that made it famous. In 1870, Benjamin F. Goodrich, a New York doctor and rubber manufacturer, moved to Akron and established a rubber factory. Several other rubber companies later built factories in Akron, and the city grew rapidly. The development of the automobile industry in the early 1900's created a huge demand for rubber tires. Akron became the world's leading tire producer. The city's population soared, rising from about 70,000 in 1910 to nearly 210,000 in 1920. Military needs during World War II (1939-1945) led to an even greater demand for Akron's tires and other rubber products.

Rubber remained the city's main industry until about the 1970's. During the 1970's and 1980's, Akron , like other older cities of the North, lost many jobs and people to newer factories in the South and Southwest. In the late 1900's, the city worked to diversify its manufacturing

base and to redevelop its downtown. Today, many small businesses occupy the buildings once dominated by the rubber industry. Kathleen M. Fraze

Aksum, *AHK soom,* also spelled *Axum,* was a powerful ancient kingdom in East Africa. It occupied lands that are now Eritrea, northern Ethiopia, parts of Sudan and Djibouti, and at times parts of southwest Arabia. Aksum was the ancestor of Ethiopia. Aksum's capital, also called Aksum, stood on the site of what is now Aksum in Ethiopia. The kingdom became important about A.D. 50 and reached its greatest strength between the 300's and 600's.

Aksum grew rich and powerful in part because of Adulis, its port on the Red Sea. Adulis was a world trading center near what is now Massawa, Eritrea. Spices, ivory, ebony, animal skins, and tortoise shells were exported from Adulis in exchange for textiles, precious metal objects, wine, and olive oil. These imports came principally from Egypt and the Mediterranean area. Aksum's trade network also included Arabia and India and may have stretched as far as China.

At its peak, Aksum conquered other kingdoms along the Red Sea and the Blue Nile River. Aksumite kings built impressive fortresses, palaces, and granite monuments. During the 300's, King Ezana conquered the kingdom of Kush in what is now Sudan. Ezana also made Christianity the state religion of Aksum.

During the 600's, Muslim conquests in Arabia, Egypt, and along the Red Sea and east African coasts ended Aksum's role as a trading power. Islam, the religion of the Muslims, spread rapidly in Arabia and North Africa. As a result, the Christians of Aksum found themselves surrounded by Muslims and other non-Christians. From the 600's to about the 900's, the Aksumites fought the Muslims. Aksum lost power and territory. However, aspects of Aksum's culture, particularly its Christian faith, survive today in Eritrea and Ethiopia. In addition, the ruins and monuments of Aksum's capital can still be seen in the present-day town of Aksum. Kevin C. MacDonald

The kingdom of Aksum about A.D. 400

Aksum, shown in yellow, occupied lands that are now Eritrea, northern Ethiopia, and parts of Sudan and Djibouti. By the middle of the A.D. 300's, Aksum had gained control of the land and sea routes from Africa to Europe and Asia. Present-day boundaries are shown as gray lines.

Alabama was the most famous of the 20 Confederate cruisers that preyed on Union merchant ships and whalers during the American Civil War (1861-1865). Together with the *Florida, Shenandoah,* and 17 other cruisers, the *Alabama* destroyed 257 Union ships. The Confederate cruisers also forced more than 700 other Union ships to travel under foreign flags to avoid attack. The raiders had little effect on the outcome of the Civil War. But their actions disrupted trade and nearly destroyed the United States Merchant Marine.

The *Alabama* was built in England in 1862. Under the command of Confederate naval hero Raphael Semmes, it sank, burned, or captured 64 ships in the next two years. In June 1864, Union warships found the *Alabama* in the harbor of Cherbourg, France, where it had gone for repairs. Captain John A. Winslow of the U.S.S. *Kearsarge* stood ready to give battle when the *Alabama* sailed into the English Channel on June 19. Within an hour, the *Kearsarge* sank the *Alabama.*

Six years after the Civil War, the British expressed regret in the Treaty of Washington for the escape of ships built or fitted out for the Confederacy in British ports. In 1872, the Geneva Tribunal of Arbitration decided that the United Kingdom had failed in its obligations of neutrality by aiding the Confederate Navy. The United Kingdom was obliged to pay the United States $15 ½ million for damages that had been inflicted on Northern shipping by the *Alabama* and other Confederate cruisers.
Gabor S. Boritt

Combat of the Kearsarge and the Alabama (about 1865), an oil painting on canvas by Edouard Manet; the Philadelphia Museum of Art, the John G. Johnson Collection

The Confederate cruiser *Alabama* was sunk by the Union warship *Kearsarge* in a battle in the English Channel in 1864.

Cliff Harden, Shostal

Forest-covered hills surround a swimming hole in Cheaha Mountain State Park, near Anniston. Scenic highlands cover much of northern Alabama. Low coastal plains lie to the south.

Alabama *The Heart of Dixie*

Alabama, one of the Southern States of the United States, is known as the *Heart of Dixie.* Alabama occupies a central place in the history of the South. The Constitution of the Confederacy was drawn up in Montgomery, the state capital, in 1861. The Alabama Capitol served as the first Confederate Capitol. There, Jefferson Davis took office as president of the Confederacy.

Today, Alabama has a vital part in the nation's future. Huntsville, called *Rocket City, U.S.A.,* is the site of the Redstone Arsenal and the George C. Marshall Space Flight Center. Scientists at Huntsville developed many important rockets and space vehicles, including the Saturn 5 rocket system that carried the first astronauts to land on the moon.

Most parts of the South did not become widely industrialized until the 1900's. But heavy industry got a relatively early start in Alabama, mainly because of the state's rich mineral resources. Northern Alabama had all three main raw materials used in making steel—coal, iron ore, and limestone. Blast furnaces for making iron and steel began operating in Birmingham in the 1880's. After that, Birmingham grew rapidly. Today, it is Alabama's largest city, and one of the state's important centers of service industries.

For many years, "King Cotton" ruled Alabama's farm economy. When the cotton crop was poor, or when it sold at low prices, Alabama farmers suffered. But serious crop failures during the early 1900's taught the farmers that they should plant a variety of crops. Then they would not lose all their money if the cotton crop failed. Alabama is still a leading cotton producer. But much livestock and poultry and large crops of corn, peanuts, and soybeans are also raised in the state.

Forest-covered hills and ridges spread over much of northern Alabama. In places where the land has been cleared, bright red clay soils add splashes of color to the landscape. Many dams along rivers and creeks help prevent floods. Hydroelectric power stations at some of the larger dams produce electricity for use in homes and factories.

In the southern part of Alabama, the hills give way to thick pine forests, rolling grasslands, and low croplands.

The contributors of this article are William D. Barnard, Professor of History Emeritus at the University of Alabama; and David C. Weaver, Chairman and Professor of Geography at the University of Alabama.

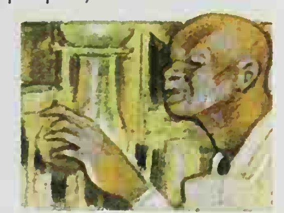
Riverchase Galleria is a popular Birmingham shopping mall. Birmingham is Alabama's largest city and an industrial center.

Interesting facts about Alabama

WORLD BOOK illustrations by Kevin Chadwick

The first electric trolley streetcars in the United States began operating in Montgomery in 1866.



Little River, located on Lookout Mountain in northeastern Alabama, is the only river in the United States that runs its entire course on the top of a mountain. It forms the Little River Canyon. Known as the "Grand Canyon of the South," it is the deepest gorge east of the Mississippi River.

First trolley streetcars

A monument to the boll weevil, erected in 1919, stands in the town of Enterprise. After the insect destroyed their cotton crops, Alabama farmers were forced to grow new and more diverse crops. As a result, the farmers became more prosperous. Enterprise then put up the monument "in profound appreciation of the boll weevil and what it has done as the herald of prosperity . . . ."

George Washington Carver gained a reputation as one of the world's greatest agricultural scientists from the research he conducted at Alabama's Tuskegee Institute (now Tuskegee University). Among his discoveries were more than 300 new uses for peanuts and more than 100 new uses for sweet potatoes.

George Washington Carver

The black civil rights movement began at the Dexter Avenue Baptist Church in Montgomery in 1955. The church's minister, Martin Luther King, Jr., organized a nonviolent protest group to help carry out a boycott against the Montgomery bus system. This action came after a black passenger was arrested for refusing to yield her seat to a white person.

The Mobile Delta area in the southern part of the state has many swamps and *bayous* (shallow channels filled with slow-moving water). At the southern tip of Alabama, sandy beaches border Mobile Bay and the Gulf of Mexico.

Mobile, at the mouth of the Mobile River, is a busy seaport. Oceangoing ships unload a wide variety of goods at the Alabama State Docks in Mobile Bay. The goods include minerals and other raw materials to be made into manufactured goods in Alabama factories. The ships carry away Alabama coal and a wide variety of the state's products, including iron and steel, petroleum products, pulp and other wood products, soybeans, and wheat.

The name *Alabama* comes from the name of an Indian tribe that once lived in the region. These Indians called themselves the *Alibamu,* meaning *I open* (or *I clear*) *the thicket.* One of Alabama's nicknames, the *Yellowhammer State,* originated during the Civil War (1861-1865). A company of Alabama troops paraded in uniforms trimmed with bits of bright yellow cloth. The soldiers reminded people of the birds called yellowhammers, which have yellow patches under their wings. After that, Alabama soldiers were known as *Yellowhammers.*

Mobile Department of Tourism

The Port of Mobile, Alabama's only seaport, lies on Mobile Bay north of the Gulf of Mexico. Cargo passing through the port includes chemicals, textiles, foods, and metal products.

Alabama in brief

Symbols of Alabama

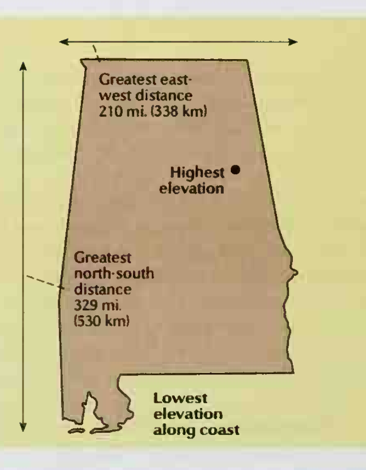
The state flag, adopted in 1895, bears a crimson cross on a white field. The flag's cross is suggestive of the Confederate battle flag. The state seal, first adopted in 1819, has a map of Alabama that shows the state's rivers and bordering states. The rivers served as important shipping routes when Alabama had few good roads. Today, the rivers remain vital to the state as sources of hydroelectric power.

State flag

State seal

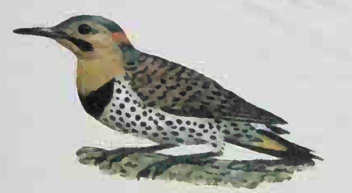
Alabama (brown) ranks 29th in size among all the states and 5th in size among the Southern States (yellow).

General information



Statehood: Dec. 14, 1819, the 22nd state.
State abbreviations: Ala. (traditional); AL (postal).
State motto: *Audemus Jura Nostra Defendere* (We Dare Defend Our Rights).
State song: "Alabama." Words by Julia S. Tutwiler; music by Edna Goeckel Gussen.

Montgomery has housed the State Capitol since 1846. Earlier capitals were St. Stephens (1817-1819), Huntsville (1819-1820), Cahaba (1820-1826), and Tuscaloosa (1826-1846).



Land and climate

Area: 51,718 sq. mi. (133,950 km²), including 968 sq. mi. (2,507 km²) of inland water but excluding 519 sq. mi. (1,343 km²) of coastal water.
Elevation: *Highest*—Cheaha Mountain, 2,407 ft. (734 m) above sea level. *Lowest*—sea level along the Gulf of Mexico.
Coastline: 53 mi. (85 km).
Record high temperature: 112 °F (44 °C) at Centreville on Sept. 5, 1925.
Record low temperature: −27 °F (−33 °C) at New Market on Jan. 30, 1966.
Average July temperature: 80 °F (27 °C).
Average January temperature: 46 °F (8 °C).
Average yearly precipitation: 56 in. (142 cm).

Important dates

- **1519** Alonso Álvarez de Piñeda sailed into Mobile Bay.
- **1702** French Canadians founded Fort Louis on the Mobile River. In 1711, the colony moved to Mobile.
- **1819** Alabama became the 22nd state on December 14.
- **1880** The state's first blast furnace began operating in Birmingham.

1933 The federal government created the Tennessee Valley Authority.

1960 The George C. Marshall Space Flight Center was established in Huntsville.

1965 Martin Luther King, Jr., led a march from Selma to Montgomery to protest discrimination in voter registration.

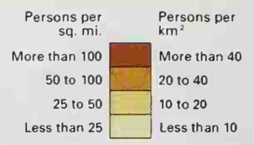
1985 Completion of the Tennessee-Tombigbee Waterway linked Alabama's port at Mobile with the Tennessee and Ohio rivers.

People

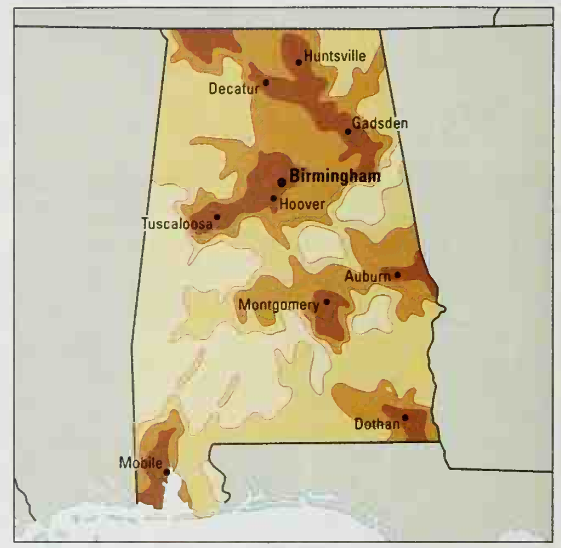
Population. The 2000 United States census reported that Alabama had 4,447,100 people. The state's population had increased 10 $\frac{1}{2}$ percent over the 1990 census figure, 4,040,587. According to the 2000 census, Alabama ranks 23rd in population among the 50 states.

About 70 percent of the people of Alabama live in metropolitan areas. These areas are Anniston, Auburn-Opelika, Birmingham, Decatur, Dothan, Florence, Gadsden, Huntsville, Mobile, Montgomery, and Tuscaloosa. The Columbus (Georgia) metropolitan area extends into Alabama. For the populations of these metropolitan areas, see the *Index* to the political map of Alabama. See Metropolitan area.

Alabama has 24 cities with populations of 20,000 or more. Birmingham, the largest city, developed as a steelmaking center. Today, Birmingham is an important center of service industries, particularly medical services.



Huntsville is the home of the U.S. Army's Redstone Arsenal and the National Aeronautics and Space Administration's George C. Marshall Space Flight Center. During the 1950's, Huntsville's population grew by 340 percent. Thousands of people moved to the Huntsville area to work on missile and space projects of the United States government.



Birmingham, Huntsville, Mobile, Montgomery, and other cities have kept the attractiveness of small communities, in spite of their rapid growth. Huge oak trees arch over wide boulevards, even in many downtown areas. Stately old homes add to the charm and dignity of these cities.

About a fourth of the people in Alabama are African Americans. Other large population groups in the state include people of Irish, English, German, and American Indian descent.

Population density

Most of Alabama's most densely populated areas lie in the east and north. Much of the swampy Mobile River Delta area of southwestern Alabama is thinly populated.

WORLD BOOK map; based on U.S. Census Bureau data.

Schools. Alabama established its public school system in 1854. Like most Southern States, Alabama had separate schools for whites and blacks. In 1954, the Supreme Court of the United States ruled that school segregation is unconstitutional. In 1963, Alabama began to desegregate its public schools. By 1973, most of these schools had been integrated.

Today, Alabama operates about 130 local public school systems. It also operates a system of secondary-level vocational technical training centers. The superintendent of education heads the state's public school system. The superintendent is appointed by the state board of education. The nine-member Board of Education establishes policies for the public school system. The gov-

ernor serves as president of the board. The other eight members are elected by the voters to four-year terms.

Alabama law requires children from age 7 through 15 to attend school. For the number of students and teachers in Alabama, see **Education** (table).

Libraries. Alabama's first large library, the Supreme Court Library in Montgomery, was created in 1828. In 1901, the state legislature created the Department of Archives and History—the first state-supported archives in the United States. Today, the largest of Alabama's public libraries are in Birmingham, Huntsville, Mobile, and Montgomery. The public library in Birmingham owns the Rucker Agee collection of rare maps, the Tutwiler collection on Southern history and literature, and a collection of civil rights documents. The University of Alabama's William Stanley Hoole Special Collections Library in Tuscaloosa has materials on the history of the region.

Museums. The Anniston Museum of Natural History includes exhibits on the history of the earth and displays of birds in their natural surroundings. The George Washington Carver Museum at the Tuskegee University National Historic Site features exhibits that illustrate contributions of blacks to U.S. history. It also displays artwork by African and African American artists. The University of Alabama State Museum of Natural History exhibits a large collection of Indian items. The collection includes prehistoric items found at Mound State Monument. The Historic Mobile Preservation Society has displays on the American Civil War period.

The Birmingham Museum of Art, the Mobile Museum of Art, the Huntsville Museum of Art, and the Montgomery Museum of Fine Arts exhibit chiefly works of art. The U.S. Army Aviation Museum at Fort Rucker has one of the largest collections of helicopters in the world.

The beaches and hotels along Alabama's Gulf Coast are among the state's major attractions. Many vacationers visit the area each year. Many enjoy saltwater fishing in the Gulf of Mexico and freshwater fishing on inland lakes. Tourists also come to see Alabama's historic homes and beautiful gardens.

One of Alabama's outstanding annual events is the Mardi Gras celebration in Mobile. The festivities begin two weeks before Shrove Tuesday. They include colorful parades through the streets both during the day and in the evening.

During late March and early April, blossoms begin to appear on shrubs along Mobile's famous Azalea Trail. This trail is an automobile route, about 35 miles (56 kilometers) long, through the city. The trail passes many of Mobile's most beautiful homes and gardens. The azaleas and other flowering shrubs are usually loveliest during late March.

Bellingrath Gardens

Bellingrath Gardens in Mobile

Places to visit

Following are brief descriptions of some of Alabama's many interesting places to visit:

Ave Maria Grotto, in Cullman, features more than 125 miniature replicas of famous buildings and religious shrines constructed on a hillside. Joseph Zoettl, a Benedictine monk, constructed most of the buildings.

Battleship *Alabama* was presented to Alabama by the U.S. government in 1964. Alabamians raised money to restore the 35,000-long-ton (35,600-metric-ton) ship, which served in World War II (1939-1945). The battleship is now anchored in Mobile Bay.

Bellingrath Gardens, in Mobile, is world famous for its displays of azaleas in the spring and chrysanthemums in the autumn. Flowers bloom in the gardens the year around. Many waterfowl populate the gardens.

Dexter Avenue King Memorial Baptist Church, in Montgomery, was the site at which Martin Luther King, Jr., first preached his message of peace and brotherhood. A huge mural in the basement of the church depicts important events in King's life.

First White House of the Confederacy, in Montgomery, was the home of President and Mrs. Jefferson Davis during the first months of the Confederacy. The white frame house was built in 1835.

McWane Center, in Birmingham, is a science center. It features exhibits that allow visitors to interact with energy, motion, light, sound, electricity, and magnetism.

Sequoyah Caverns, at Valley Head, contain beautiful rock formations and clear, shining lakes. Lighting inside the caverns creates interesting reflections of the formations in the water.

U.S. Space and Rocket Center, at Tranquility Base in Huntsville, houses a large collection of spacecraft, rockets, and hands-on astronaut training exhibits.

National forests, parks, and monuments. Alabama has four national forests: Talladega, William B. Bankhead, Conecuh, and Tuskegee. Talladega, the largest, has two divisions—one in central Alabama and the other in eastern Alabama.

Horseshoe Bend National Military Park, near Dadeville, marks the site where Andrew Jackson defeated the Creek Indians in 1814. Natchez Trace Parkway between Natchez, Mississippi, and Nashville, Tennessee, runs across northwestern Alabama. This parkway, which is administered by the National Park Service, follows a route that was used by pioneers to return north after floating goods down the Mississippi River on flatboats (see Natchez Trace).

At Russell Cave National Monument near Bridgeport, archaeologists have found tools and other items used by prehistoric people. These items show that people lived in the cave as early as 7000 B.C., and that the cave was used as a shelter until about A.D. 1650.

State parks. Alabama has 24 state parks and 2 state historical ironworks parks. The Alabama Historical Commission operates Fort Morgan on Mobile Bay. For further information on Alabama's state parks and lakes, write to Commissioner, State Department of Conservation and Natural Resources, Montgomery, AL 36130.

Mardi Gras in Mobile

Annual events

January-May
Mardi Gras in Mobile (February-March); Zoo Weekend in Montgomery (March); Selma Pilgrimage Weekend (March); Eufaula Pilgrimage (April); Birmingham Festival of Arts (April); Panoply, a festival of the visual and performing arts, in Huntsville (May); Jubilee Cityfest, Montgomery (May).

June-August
City Stages in Birmingham (June); America's Junior Miss in Mobile (late June); Chilton County Peach Festival in Clanton (June); W. C. Handy Music Festival in Florence (early August).

September-December
Big Spring Jam in Huntsville (September); South Alabama National Fair in Montgomery (October); National Shrimp Festival in Gulf Shores (October); Winston 500 in Talladega (October); National Peanut Festival in Dothan (November); Annual Thanksgiving Day Pow Wow in Atmore (November); Victorian Front Porch Christmas in Opelike (December).

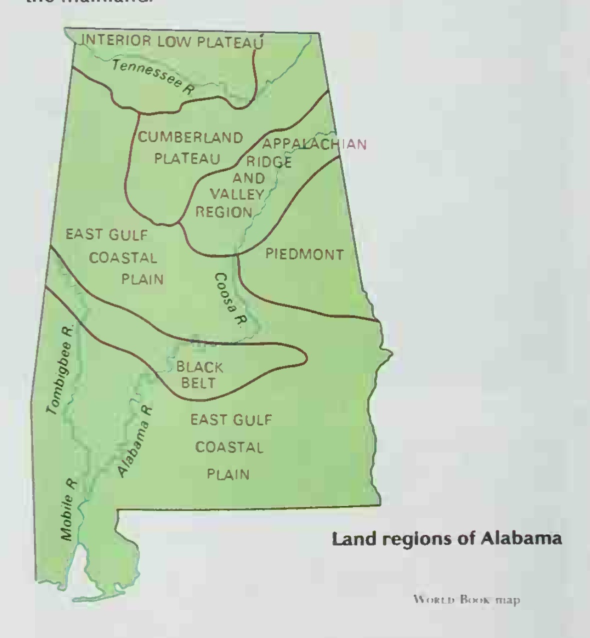
Land regions. Most of southern Alabama lies less than 500 feet (150 meters) above sea level. The surface of the state rises gradually toward the northeast. Alabama has six main land regions: (1) the East Gulf Coastal Plain, (2) the Black Belt, (3) the Piedmont, (4) the Appalachian Ridge and Valley Region, (5) the Cumberland Plateau, and (6) the Interior Low Plateau.

The East Gulf Coastal Plain is Alabama's largest land region. It covers the entire southern two-thirds of the state, except for a narrow strip of land called the Black Belt. In western Alabama, the plain extends north almost to Tennessee.

The plain has several sections. The low, swampy land of the *Mobile River Delta* makes up the southwestern section. The southeastern part is called the *Wiregrass* area. It is named for a tough grass that once grew there in pine forests. Today, the Wiregrass area is an important farming region. The northern part of the plain is often called the *Central Pine Belt* because many pine forests cover its low, rolling hills. In the western part of this section, the soils are gravelly and sandy, and are not good for growing crops.

The Black Belt is a narrow strip of rolling prairie wedged between the northern and southern parts of the East Gulf Coastal Plain. The Black Belt was named for the sticky black clay soils of its rolling uplands. Early in Alabama's history, farmers developed large plantations in this region. Boll weevils came to the Black Belt in 1915, and damaged the cotton crop. Some farmers then changed from growing cotton to raising livestock.

The Piedmont, in east-central Alabama, is an area of low hills and ridges separated by sandy valleys. The clay soils of these hills and ridges have been badly eroded. Most of the land is forested. Cheaha Mountain, the highest point in Alabama, rises 2,407 feet (734 meters) on the northwestern edge of the Piedmont.



Deposits of coal, iron ore, limestone, and marble, together with electric power from projects on the Coosa and Tallapoosa rivers, make the Piedmont an important manufacturing area. Textile production is the main industry in many small cities of the region.

The Appalachian Ridge and Valley Region is an area of sandstone ridges and fertile limestone valleys. It lies northwest of the Piedmont. The region has coal, iron ore, and limestone—the three basic minerals used in making iron and steel. For this reason, Birmingham and other large cities in the region developed as centers of iron and steel production.

The Cumberland Plateau, also known as the *Appalachian Plateau,* lies northwest of the Appalachian Ridge and Valley Region. The surface varies from flat to gently rolling land. It reaches a height of about 1,800 feet (549 meters) above sea level in the northeast. The land slopes to about 500 feet (150 meters) where it meets the East Gulf Coastal Plain in the southwest. Farmers could not grow large crops in the plateau's sandy soils until the 1880's, when commercial fertilizers came into common use. Today, farmers raise hogs and poultry there, and grow cotton, hay, potatoes, and vegetables.

The Interior Low Plateau lies in the northwestern part of the state. Much of the land is in the valley of the Tennessee River. Farmers in the region grow corn, cotton, and hay. The plateau has water transportation and hydroelectric power, which encourage manufacturing there. Decatur and "The Shoals," the area of Muscle Shoals, Florence, Sheffield, and Tuscumbia, are industrial centers.

Coastline. Alabama's general coastline extends for 53 miles (85 kilometers) along the Gulf of Mexico. The tidal shoreline, which includes small bays and inlets, is 607 miles (977 kilometers) long. Mobile Bay, at the mouth of the Mobile River, is the chief feature of the Alabama coastline. It is an important harbor area. Mississippi Sound borders the coast west of Mobile Bay. Perdido Bay is at the border between Alabama and Florida. The long, sandy peninsula between Mobile and Perdido bays is known as the *Gulf Coast.* Dauphin Island, Alabama's largest coastal island, lies at the entrance to Mobile Bay. An overseas highway connects the island with the mainland.

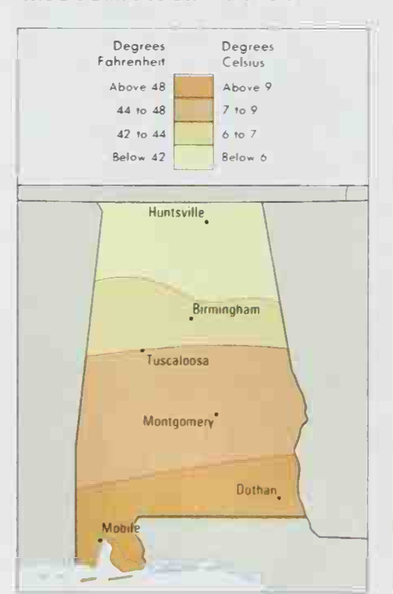
Colorful wildflowers bloom on Dauphin Island, off the coast of Alabama south of Mobile Bay. The island has beautiful beaches that attract many visitors.

Helen Kittinger, Hillstrom Stock Photo

Rivers and lakes. Navigable rivers flow through almost every part of Alabama. The Mobile River and its tributaries flow south to the Gulf of Mexico. They form the most important river system in the state. The Alabama and the Tombigbee, Alabama's longest rivers, meet about 45 miles (72 kilometers) north of Mobile and form the Mobile River. The Alabama River begins where the Coosa and Tallapoosa rivers meet, just north of Montgomery. The Tombigbee starts in Mississippi and flows southeast into Alabama. Its main tributary in Alabama is the Black Warrior.

The Chattahoochee River forms much of the border between Alabama and Georgia. The Tennessee River is the most important river in northern Alabama. It flows west across almost the entire width of the state.



Alabama has no large natural lakes, but dams on rivers have created many artificial lakes. The largest of these, Guntersville Lake, covers 110 square miles (285 square kilometers). It is formed by Guntersville Dam on the Tennessee River. Other large artificially created

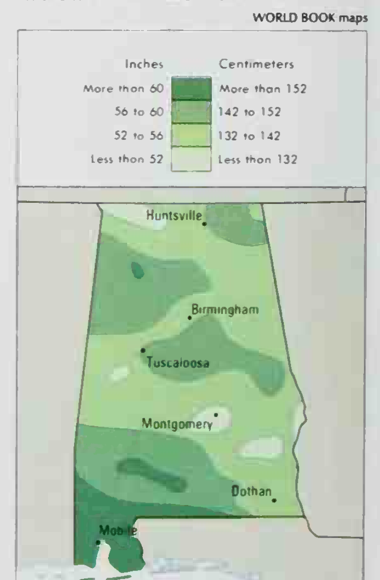
Average January temperatures

In winter, winds from the Gulf of Mexico bring mild air to southern Alabama. Winters are a little colder in the north.

Average July temperatures



Summers in Alabama are long, hot, and humid. Higher elevations make the northeast slightly cooler.

Average yearly precipitation

Alabama receives much rainfall, especially near the Gulf coast. Snowfall is light in the north and rare in the south.

WORLD BOOK maps

lakes, in order of size, include Wheeler on the Tennessee River, Martin on the Tallapoosa River, and Weiss on the Coosa River.

Plant and animal life. Forests cover about two-thirds of Alabama. Pine forests are the most common type of forest. Besides pines, other trees in the state include cedars, cypresses, hemlocks, and oaks.

In the spring, blooming shrubs and trees cover the Alabama countryside. The state is famous for its azaleas. It also has flowering dogwood, mountain laurel, and rhododendrons. Alabama's wildflowers include asters, Dutchman's-breeches, goldenrods, orchids, pinks, and southern camasses.

Bobcats, deer, red and gray foxes, minks, opossums, rabbits, raccoons, skunks, squirrels, and wild turkeys live in many parts of Alabama. Beaver colonies thrive in the swamps and lowlands. Some alligators can be found in the state's southern swamps and bayous (see **Bayou**). These areas also provide winter shelter for ducks, geese, and other water birds that fly north in the spring. Freshwater fish in Alabama streams include bass, bream, buffalo fish, catfish, crappies, garfish, and shad. Drumfish, flounder, mackerel, mullet, red snapper, and tarpon are common in the Gulf of Mexico along Alabama's coast. Shellfish found in the Gulf include crabs, oysters, and shrimps.

Climate. Alabama has a mild climate. January temperatures average about 52 °F (11 °C) in the southern part of the state, and about 46 °F (8 °C) in the north. July temperatures average about 80 °F (27 °C) throughout the state. Alabama's lowest temperature, −27 °F (−33 °C), occurred at New Market on Jan. 30, 1966. The highest temperature, 112 °F (44 °C), was at Centreville on Sept. 5, 1925. Alabama's annual *precipitation* (rain, melted snow, and other moisture) averages from about 65 inches (165 centimeters) on the coast to 53 inches (135 centimeters) in the north. Snow falls in the north, but is rare on the coast.

Economy

As in many states, Alabama's economy is changing. Alabama has long been known for its manufacturing industries. Manufacturing remains the state's single most important economic activity in terms of the *gross state product*—the total value of all goods and services produced in a state in a year. However, the number of manufacturing jobs in the state declined during the 1990's. Service industries, taken together, make up the largest portion of Alabama's gross state product. In the 1990's, these industries had significant job growth.

Mining and farming also contribute to Alabama's economic output. The state is an important producer of coal and natural gas. Much of its agricultural income is produced by farms that raise livestock.

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Manufacturing	20	391,500	16

*GSP = gross state product, the total value of goods and services produced in a year. Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

Natural resources of Alabama include thick pine forests, areas of fertile soil, valuable mineral deposits, and deep rivers.

Soil. Alabama's Black Belt is known for its black clay soils. Parts of the East Gulf Coastal Plain have sandy soils. Red soils cover most other parts of the state. In many areas, these red soils were once covered by gray or yellow topsoil. Much of the fertile topsoil was carried away by erosion after farmers cut down trees and plowed the land. Today, many Alabama farmers help save fertile soils by contour plowing, terracing, and other conservation methods.

Minerals. Valuable deposits of coal and limestone lie fairly close together in the Birmingham area of Alabama. These materials are used in the production of iron and steel. Alabama's most important coal beds are located in the north-central part of the state. Major deposits of limestone are also found in northern Alabama.

Alabama has important oil and natural gas fields in Choctaw, Escambia, Mobile, and other southwestern counties. Other mined products found in the state include asphalt, bauxite, clay, dolomite, marble, mica, salt, sand and gravel, sandstone, and talc.

Service industries, as a group, contribute the greatest part of the gross state product in Alabama. Most of the service industries are concentrated in the state's metropolitan areas.

Ranking first among Alabama's service industries are (1) community, business, and personal services and (2) wholesale and retail trade. Each contributes an equal amount toward the gross state product.

Community, business, and personal services consist of a variety of establishments, including private health care, law firms, software developers, and engineering companies. Blount, an important construction engineering company, is based in Montgomery. Birmingham is a center for high-tech and telecommunications services.

The wholesale trade of groceries, machinery, and mined products is important in Alabama. Mobile serves as the state's major center of wholesale trade. Major types of retail businesses include automobile dealerships, discount stores, and food stores. Bruno's, one of the South's largest grocery store chains, is headquartered in Birmingham.

Government ranks next among the service industries of Alabama. Government services include the operation of public schools, public hospitals, and military establishments. The public school system is a leading employer in Alabama. Major military bases located in the state include Fort Rucker, near Dothan, and Maxwell Air Force base and Gunter Annex, near Montgomery. The Huntsville area is home to the George C. Marshall Space Flight Center and the Redstone Arsenal. State government offices are based in Montgomery.

Finance, insurance, and real estate forms Alabama's fourth-ranking service industry. Birmingham is Alabama's leading financial center. Two of the South's largest banking companies, Amsouth and SouthTrust, have their headquarters there. Large financial companies are also based in Montgomery. Real estate is a major part of the economy of Alabama because of the large sums of money involved in the buying and selling of homes. The leasing of buildings is also part of the real estate sector.

Transportation, communication, and utilities ranks fifth among service industries in Alabama. Many shipping companies are based in Mobile, which has one of the busiest ports in the United States. Ships transport the state's mined products and many other types of freight. Trucking and shipping companies also transport much of Alabama's freight. Pipeline companies transport petroleum and natural gas. Telephone companies are the most important part of the communications sector. The Alabama headquarters of BellSouth are in Birmingham. Utility companies provide electric, gas, and water service. More information about transportation and communication appears later in this section.

Manufacturing. Goods manufactured in Alabama have a *value added by manufacture* of about $30 billion yearly. This figure represents the increase in value of raw materials after they become finished products.

Ed Malles, Hillstrom Stock Photo

Paper mills operate in many parts of Alabama. Paper products rank among Alabama's leading manufactured goods. The state is a major U.S. producer of forest products.

Chemicals are Alabama's leading manufactured goods in terms of value added by manufacture. The state's most important chemical products are used by industry. Alabama factories also produce chemical fibers, fertilizers, and insecticides. Chief chemical production centers in the state include Decatur and Mobile.

Paper products rank second in value added among Alabama's manufactured products. Pulp and paper are produced at mills in many parts of the state, including the Mobile, Montgomery, and Childersburg areas. Other paper products manufactured in Alabama include cardboard, paper bags, and paper tissue.

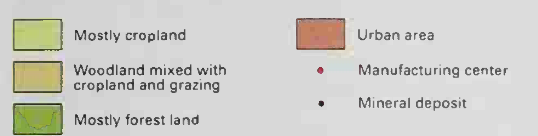
Primary metals are Alabama's third-ranking manufactured product. Primary metals manufacturing is based mainly on the steel industry, which is centered in Birmingham, Decatur, and Gadsden.

Transportation equipment is Alabama's fourth-ranking manufactured product. Motor vehicles, aircraft engines, and military and space equipment are produced here.

Food products rank fifth in terms of value added by manufacture. The state's major food processing activities include bread baking and meat packing.

Other goods made in Alabama include clothing, computer and electronic equipment, fabricated metal products, machinery, rubber and plastic products, textiles, and wood products. Much of the clothing made in Alabama is manufactured in small towns, including Andalusia, Bay Minette, Elba, Haleyville, Jasper, and Scottsboro. Computer components and communications equipment are the leading types of electronic equipment made in Alabama. The state's fabricated metal products include hardware, containers, and architectural metals. Factories in Birmingham and Montgomery manufacture heating and air conditioning units. Florence is a center for the manufacture of metalworking machinery. Huntsville, Opelika, and Tuscaloosa have large tire factories. Plants near Birmingham and Huntsville make a variety of plastic products. Fabric, thread, yarn, and other textile products are made in many parts of Alabama. Lumber, plywood, and veneers are among the state's chief wood products.

Agriculture. Farms cover about 30 percent of Alabama's land area. The state has approximately 49,000 farms.



Livestock products account for about three-fourths of Alabama's farm income. Alabama ranks among the leading states in the production of *broilers* (chickens 5 to 12 weeks old). Broilers are the most valuable farm product in the state. They provide more than 40 percent of the farm income. Counties in the northern part of the state produce the most broilers.

Beef cattle are Alabama's second most valuable farm product. Cattle graze on grasslands throughout the state, but especially in the Black Belt in central Alabama. Eggs and milk are also leading livestock products in the state. Hogs are raised in all parts of the state, but especially in the Wiregrass area. Catfish farming and beekeeping are also important in Alabama.

Until the early 1900's, cotton production employed many farmworkers and provided almost all of Alabama's agricultural wealth. Today, cotton is still Alabama's leading crop, and the state is a leading cotton producer. Mechanical pickers harvest much of the cotton crop.

Economy of Alabama

This map shows the economic uses of land in Alabama and where the state's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

Greenhouse and nursery products are an important source of farm income. Peanuts, which are grown in the Wiregrass region, are another important crop. Other valuable field crops include corn, soybeans, and wheat.

Peaches are produced mainly in Chilton county. Alabama farmers also grow apples, nectarines, plums, grapes, strawberries, and blueberries. The state's leading vegetable crops include potatoes, sweet potatoes, sweet corn, tomatoes, and watermelons. Most of the potatoes and sweet potatoes are produced in Baldwin, Chilton, Cullman, DeKalb, and Jackson counties. Pecans are another valuable farm product, produced mainly in the southern part of the state.

Mining. Alabama's most valuable mined products are coal, natural gas, petroleum, crushed stone, and limestone. Jefferson, Tuscaloosa, and Walker counties in north-central Alabama produce most of the state's coal. The coal is a *bituminous* (soft) variety that is taken from both underground and surface mines. Natural gas and petroleum are obtained mainly from wells in the southwestern part of the state. The production of methane gas from coal is a major activity in west-central Alabama. Large limestone quarries lie near Birmingham and Huntsville. Limestone is used primarily to make cement and roadbeds.

Alabama is among the leading states in mining bauxite and marble. The state's other mined products include clays, salt, and sand and gravel.

Fishing industry. Alabama has an annual fish catch valued at about $50 million. The Gulf of Mexico provides most of the catch. Shrimp are the most valuable product of Alabama's saltwater fishing industry. Blue crabs rank second in value, followed by oysters. Buffalo fish, catfish, and mussels are caught commercially in freshwater streams in Alabama. Grain-fed catfish, raised in artificial ponds on farms, are an important new food crop.

Electric power. Plants that burn coal provide about two-thirds of Alabama's electric power. Nuclear plants provide about 25 percent of the state's electric power. Hydroelectric plants supply almost all of the remaining power. The Tennessee Valley Authority, a government corporation, operates hydroelectric and nuclear plants in northern Alabama.

Transportation. Alabama has about 94,000 miles (151,000 kilometers) of roads and highways. Four major rail lines provide freight service in Alabama. Passenger trains serve Birmingham and two other cities in the state. Most of Alabama's air traffic goes in and out of airports at Birmingham, Huntsville, and Mobile.

About 1,350 miles (2,170 kilometers) of navigable waterways cross the state. They include a section of the Gulf Intracoastal Waterway between Brownsville, Texas, and Carrabelle, Florida. This section is about 60 miles (97 kilometers) long. The Black Warrior-Tombigbee-Mobile river system, 453 miles (729 kilometers) long, is the longest navigable waterway in Alabama. The Tennessee River connects northern Alabama with the Mississippi River system. The 234-mile- (377-kilometer-) long Tennessee-Tombigbee Waterway was completed in 1985. This waterway helps link the port at Mobile with inland ports on the Tennessee and Ohio rivers. Alabama has built dock facilities at Decatur, Eufaula, Huntsville, Phenix City, and other towns along waterways.

Mobile, on Mobile Bay, is Alabama's only seaport. The Alabama State Docks at Mobile are among the finest port facilities in the United States. They can handle about 35 oceangoing vessels at a time.

Communication. *The Mobile Register,* founded in 1813, is Alabama's oldest newspaper. Today, about 130 newspapers, including about 25 dailies, are published in Alabama. *The Birmingham News* has the largest circulation. Other leading papers include the *Birmingham Post-Herald, The Huntsville Times,* the *Mobile Register,* and *The Montgomery Advertiser.* About 90 periodicals are also published in Alabama.

WAPI of Birmingham is Alabama's oldest commercial radio station. It began in 1922 in Auburn as WMAV. WVTM-TV, the state's first television station, was established in Birmingham in 1949 as WABT-TV. The Alabama Public Television Network began operating in 1955. It was the first state-owned educational television system in the nation. This system has stations in several cities and reaches every county in the state. Alabama has about 225 radio stations and 35 television stations. Cable TV systems and Internet providers serve most areas.

Government

Constitution of Alabama was adopted in 1901. The state had five earlier constitutions, adopted in 1819, 1861, 1865, 1868, and 1875. An amendment may be proposed either by the Alabama Legislature or by a constitutional convention. An amendment proposed by the Legislature must be approved by three-fifths of the members in each house. Then it must get the approval of a majority of the electors voting on the issue. Alabama's Constitution has been amended over 600 times, the most of any state constitution.

A majority of the members of each house of the legislature and a majority of the voters must approve calling a constitutional convention. An amendment proposed by the convention must be approved by a majority of the people voting on the issue in an election.

Executive. The governor of Alabama is elected to a four-year term. This official can serve more than one term. However, the governor is not allowed to serve three terms in a row. Alabama's other top executive officials include the lieutenant governor, secretary of state, attorney general, auditor, treasurer, and commissioner of agriculture and industries. Each of these officials is elected to a four-year term.

Legislature consists of a Senate of 35 members and a 105-member House of Representatives. Each of Alabama's 35 senatorial districts elects one senator. Each of the state's 105 representative districts elects one member to the House of Representatives. Senators and representatives serve four-year terms.

The Legislature holds regular sessions each year. Sessions may not last longer than 105 days, and the Legislature may not meet as a whole on more than 30 of these days. Sessions begin in January during the first year of the legislative term, in February during the second and third years, and in April during the fourth year.

Courts. The highest court in Alabama is the state Supreme Court. It has a chief justice and eight associate justices, and they are all elected to six-year terms. The Court of Criminal Appeals has five judges, and the Court of Civil Appeals has five judges. These judges also are all elected to six-year terms. Lower courts in Alabama include a circuit court, district court, probate court, and municipal courts.

Local government. Alabama has 67 counties. Each is governed by a board of commissioners. The boards are

State Legislature

The Alabama Senate meets in the State Capitol in Montgomery. Each of Alabama's 35 state senators serves a four-year term.

The governors of Alabama

	Party	Term		Party	Term

*Democratic-Republican

known officially as county commissions. In most counties, the chief official is the probate judge. The probate judge is elected to a six-year term. Other county officials include the sheriff, district attorney, superintendent of education, engineer, tax assessor, and tax collector.

Most Alabama municipalities have a mayor-council form of government. A few cities operate under a city-manager plan. Birmingham, Huntsville, Montgomery, and Tuscaloosa have mayor-council governments. Most small cities and towns also operate under the mayor-council plan.

Revenue. Taxation provides about half of Alabama's *general revenue* (income). Most of the rest comes from federal grants and interest earned on public accounts. The main sources of tax revenue are personal and corporate income taxes, and general sales and use taxes. Other major sources of tax revenue include taxes on alcoholic beverages, insurance premiums, motor fuels, and public utilities. Taxes are also assessed for motor vehicle licenses and business licenses.

Politics. As in other Southern states, most candidates elected to national, state, and local offices in Alabama have been Democrats. Most of Alabama's major state and local political battles have traditionally been waged in primary elections for the Democratic nomination. But since the mid-1900's, Alabamians have elected a number of Republican candidates to local offices and to the Congress of the United States. In 1986, Guy Hunt became the first Republican to be elected governor of Alabama since the early 1870's.

Until the 1960's, Alabama voters usually supported Democratic presidential candidates. But in 1964, the state voted for Senator Barry M. Goldwater of Arizona, the Republican candidate. It was the first time since 1872 that the state of Alabama supported a Republican presidential candidate. Since 1980, the Republican candidate has won Alabama's electoral votes in each presidential election. For Alabama's electoral votes and voting record in presidential elections since 1820, see **Electoral College** (table).

History

Indian days. Cliff-dwelling Indians lived in the Alabama region 8,000 years ago. Excavations in Russell Cave, in northeastern Jackson County, have revealed details of their lives. Later the Cherokee, Creek, Choctaw, and Chickasaw Indians lived in the region. Whites called these groups the Civilized Tribes because they adopted many European customs. See **Five Civilized Tribes.**

Exploration and settlement. Alonso Álvarez de Piñeda, a Spanish explorer, sailed into Mobile Bay in 1519. In 1528, an expedition led by Panfilo de Narvaez passed through Alabama coastal waters. Álvar Núñez Cabeza de Vaca, the first European to cross North America, was a member of this expedition. Hernando de Soto, another Spaniard, led an expedition into the Alabama region from the northeast in 1540. He became the first white person to explore the interior. De Soto (also called Soto) and the Indians fought a bloody battle at Mabila, north of present-day Mobile. De Soto's forces defeated Chief Tuscaloosa and his warriors.

In 1559, Tristán de Luna, a Spanish adventurer from Mexico, searched for gold in the Alabama region. He organized small settlements on Mobile Bay and at the present site of Claiborne. In 1561, he was removed from his command and was forced to return to Mexico.

The first permanent group of white settlers in the Alabama region were French. In 1699, two French-Canadian brothers, Pierre Le Moyne, Sieur d'Iberville, and Jean Baptiste Le Moyne, Sieur de Bienville, sailed to Dauphin Island in Mobile Bay. In 1702, they founded Fort Louis nearby along the Mobile River. Fort Louis became the capital of the French colony known as Louisiana. In 1711, river floods forced the French to move 27 miles (43 kilometers) south to the present site of Mobile. This settlement, also called Fort Louis, became the first permanent white settlement in Alabama. It was renamed Fort Condé in 1720. The settlement was the capital of French Louisiana until 1722, when New Orleans became the capital.

In 1763, the French gave most of their colony of Louisiana to Britain in the Treaty of Paris. This treaty ended the French and Indian War. The Mobile area became part of West Florida, under British control. Northern Alabama was included in the Illinois country, a region in what is now the central United States.

In 1779, Spain declared war on Britain. In 1780, Bernardo de Gálvez captured Mobile from the British. In the Treaty of Paris signed in 1783, Britain gave the Mobile region to Spain.

Territorial days. In 1795, Thomas Pinckney, a U.S. statesman, negotiated the Treaty of San Lorenzo. This treaty, also called the Pinckney Treaty, fixed the southern boundary of the United States along the 31st parallel of north latitude. All of present-day Alabama except the Mobile area lay north of the line and became part of the United States. In 1798, the Alabama region, except the Mobile area, became part of the Mississippi Territory organized by the U.S. Congress.

During the War of 1812 against Britain, the United States seized the Mobile area from Spain. On April 15, 1813, the Stars and Stripes flew over the entire Alabama region for the first time. Also in 1813, the Creek Indians massacred several hundred pioneers at Fort Mims near Tensaw. In 1814, U.S. forces under General Andrew Jackson defeated the Creek in the Battle of Horseshoe Bend. The Creek then surrendered their land to the United States. William Weatherford, a Creek chief also known as Red Eagle, led the tribe in its bitter fight against Jackson's troops.

In 1817, the Alabama Territory was organized. St. Stephens, on the Tombigbee River, was the capital.

Early statehood. A constitutional convention met in Huntsville in 1819 and drew up the territory's first Constitution. On Dec. 14, 1819, Alabama entered the Union as the 22nd state. Huntsville served as the capital of Alabama for a little more than a year. William Wyatt Bibb, who had been governor of the Alabama Territory, became the new state's first governor. Cahaba became the capital in 1820. In 1825, floods from the Alabama River caused great damage to Cahaba. Because of the floods, the capital was moved to Tuscaloosa in 1826.

From a painting by Alonzo Chappel, from "The Pageant of America" series, Yale University Press, United States Publishers Assoc., Inc., sole distributors

Fort Mims, near Tensaw, was the site of a bloody battle. On Aug. 30, 1813, the Creek Indians led by Chief Red Eagle attacked the fort and killed several hundred pioneers.

In 1838, federal troops marched into the remaining Indian territory of Alabama, in the northeast section of the state. They demanded that all the Indians move to the west. By 1840, all but a few scattered tribes had moved west beyond the Mississippi River.

Alabama suffered severe financial troubles during the 1840's and 1850's. The state bank, created during the 1820's, was poorly managed. The bank issued too much money and, as a result, the money decreased in value. The bank also loaned large amounts of money for political reasons. In 1837, a financial panic and depression swept across the United States. The Alabama state bank could not afford to pay back the money it owed to its depositors. For this reason, Governor Benjamin Fitzpatrick began to *liquidate* (close) the bank during the early 1840's. Many Alabamians lost all their savings. The state also suffered from a drought that ruined crops, and from several epidemics of yellow fever.

During the 1840's, many people in the North wanted the federal government to outlaw slavery in the nation's western territories. In 1848, a Democratic state convention in Alabama adopted the "Alabama Platform" supported by William L. Yancey, a prominent statesman. This platform declared that the federal government did not have the right to bar slaves from the territories.

The Civil War and Reconstruction. Disagreements over slavery continued during the 1850's. Economic rivalries between the agricultural South and the industrial North and disagreements about the rights of states also created conflicts (see **States' rights**). These conflicts deepened after Abraham Lincoln was elected President in 1860. Alabama *seceded* (withdrew) from the Union on Jan. 11, 1861, and declared itself the Republic of Alabama. The Alabama secession convention invited other Southern States to send delegates to Montgomery. On February 8, the convention established the Confederate States of America, with Montgomery as its capital. For this reason, Montgomery is known as the *Cradle of the Confederacy.* The capital of the Confederate States was moved to Richmond, Va., in May 1861.

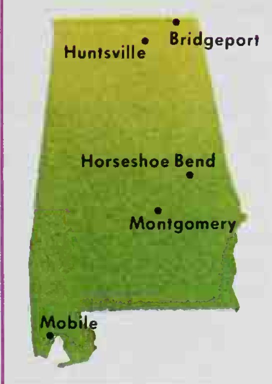
The most important Civil War action in the state was the Battle of Mobile Bay in 1864, won by Union forces under Rear Admiral David G. Farragut (see **Farragut, David G.**). Union forces also made several raids into Alabama during the war. In 1863, Confederate forces led by General Nathan Bedford Forrest captured a much larger group of Union raiders at Cedar Bluffs. In 1865, Union General James H. Wilson led the largest raid into Alabama and won victories at Selma and Montgomery.

Most of Alabama escaped the ruin that spread across the South during the Civil War. However, Florence, Huntsville, Montgomery, Selma, and other cities in the northern and central parts of the state suffered destruction and looting.

Alabama faced mounting financial problems during the Reconstruction period that followed the war. The state debt increased from $8 million to more than $32 million from 1866 to 1873. The state government came under the control of former Northerners called *carpetbaggers* and Southerners called *scalawags.* On June 25, 1868, Alabama was readmitted to the Union. In 1874, conservative Democrats succeeded in electing most state officials. The state government was reformed, and a new constitution was adopted in 1875.

State prosperity followed the Reconstruction period. During the 1870's, several railroads were completed. Also during the 1870's, Alabamians proved they could make iron by burning iron ore with coke, rather than with charcoal. This was important because north-central Alabama had large deposits of coal, from which coke is made. The same region also had vast supplies of iron ore and limestone, the two other minerals needed to make iron and steel. In 1880, Alabama's first blast furnace, Alice No. 1, began operating in Birmingham. Within a few years, Birmingham became a great iron and steel center. Important iron and steel works were also built in Anniston, Bessemer, Decatur, Russellville, and Talladega. By 1890, iron and steel making had become Alabama's most important manufacturing industry. The lumber industry and the textile industry also grew rapidly in the late 1800's.

World War I and the Great Depression. Alabama's industry and commerce grew after the United States entered World War I in 1917. Shipbuilding became an important industry in Mobile. Alabama farmers increased production of cotton and food to meet the demands of the war effort. In the mid-1920's, the Alabama State Docks agency built new port facilities at Mobile. Alabama's trade with other countries increased greatly as a result. In 1929, the Alabama-Tombigbee river system flooded large areas in southern Alabama, causing about $6 million damage.



Many Alabamians suffered financial setbacks during the Great Depression of the 1930's. Between 1929 and 1931, more than 60 Alabama banks failed, with a loss of more than $16 million. During the early 1930's, Alabama passed a state income tax law and the Budget Control Act to help save the state from bankruptcy.

In 1933, the federal government created the Tennessee Valley Authority (TVA). The TVA was given the responsibility of building flood-control and electric-power projects on the Tennessee River. The TVA took over Wilson Dam and two nitrate plants at Muscle Shoals. The dam and plants had been built by the government

Historic Alabama

Russell Cave, in northeastern Jackson County, was the home of cliff-dwelling Indians 8,000 years ago. Excavations at the cave, now part of Russell Cave National Monument, have revealed details of their lives.

Redstone Arsenal, near Huntsville, was established in 1941. It is the headquarters of the U.S. Army Aviation and Missile Command and the George C. Marshall Space Flight Center.

The first Confederate Capital was Montgomery, from Feb. 8 to May 21, 1861. Jefferson Davis was inaugurated there.

The Union won an important Civil War battle at Mobile Bay on Aug. 5, 1864. During the battle, Union Commander David G. Farragut reportedly cried, "Damn the torpedoes! Full speed ahead!"

The Creek Indians were defeated by U.S. troops led by General Andrew Jackson in the Battle of Horseshoe Bend in 1814. The Creek then surrendered their Alabama land.

Important dates in Alabama

1519 Alonso Álvarez de Piñeda sailed into Mobile Bay.

1540 Hernando de Soto explored much of what is now Alabama.

1559 Tristán de Luna established several temporary settlements in what is now Alabama.

1702 French Canadians founded Fort Louis on the Mobile River. In 1711, the colony moved to what is now Mobile.

1763 France gave the Alabama region to Britain.

1783 Britain gave the United States much of what is now Alabama. It gave the Mobile region to Spain.

1795 The United States and Spain signed the Treaty of San Lorenzo, setting the southern boundary of the United States at the 31st parallel, across Alabama.

1813 The United States captured Mobile Bay from Spain.

1814 The Creek Indians surrendered nearly half the present state of Alabama to the United States.

1817 The Alabama Territory was created.

1819 Alabama became the 22nd state on Dec. 14.

1861 Alabama seceded from the Union on Jan. 11 and became the Republic of Alabama until Feb. 8, when it joined the Confederacy.

1868 Alabama was readmitted to the Union on June 25.

1880 The state's first blast furnace began operating in Birmingham.

1901 The present state constitution was adopted.

1933 The federal government created the Tennessee Valley Authority.

1940's The Redstone Arsenal at Huntsville became a center of rocket and spacecraft research.

1956 A federal court ordered Montgomery to desegregate its public bus system.

1960 The George C. Marshall Space Flight Center was established in Huntsville.

1965 Civil rights leader Martin Luther King, Jr., led a march from Selma to Montgomery to demonstrate the demands of blacks for an end to discrimination in voter registration.

1974 George C. Wallace became the first Alabama governor to be elected to a third term. He won a fourth term in 1982.

1985 Completion of the Tennessee-Tombigbee Waterway linked the Alabama port of Mobile with ports on the Tennessee and Ohio rivers.

during World War I and the 1920's. The TVA later built Wheeler and Guntersville dams on the Tennessee River. The Alabama Power Company, a private firm, also built dams and hydroelectric plants during the 1930's. These plants provided inexpensive power for Alabama factories, and so boosted the state's industrial growth.

The mid-1900's. During World War II (1939-1945), Alabama's agricultural and industrial production expanded greatly. The government established the Redstone Arsenal in Huntsville in 1941. The arsenal developed the rockets, satellites, and spacecraft that launched the United States into the space age.

After the war, Alabama became an important producer of chemicals, minerals, rubber products, and textiles. Alabama's industrial growth slowed down during the 1950's, and many Alabamians left the state to find jobs in the North and West. Iron ore production in Alabama dropped sharply during the 1950's. By the early 1960's, most of Alabama's iron ore mines had closed.

During the 1950's and 1960's, Alabama farmers became less dependent on cotton. Farm income came increasingly from broiler chickens, cattle, hogs, peanuts, and soybeans. As agricultural methods and products changed, fewer farmworkers were needed. Many moved to the cities, and Alabama became mainly an urban state.

Like many other states, Alabama faced serious racial problems in the 1950's and 1960's. In 1955 and 1956, civil rights leader Martin Luther King, Jr., directed the Montgomery bus boycott. Many blacks refused to ride in public buses in Montgomery because the law required them to sit in the rear. In 1956, a federal court ordered Montgomery to desegregate its buses.

In 1954, the Supreme Court of the United States had ruled that compulsory segregation in public schools was unconstitutional. But in 1963, Governor George C. Wallace personally tried to halt the integration of Alabama's public schools. In June, he stood in the doorway of Foster Auditorium at the University of Alabama in Tuscaloosa and refused to admit two blacks. President John F. Kennedy called the National Guard to active duty, and the troops enforced the law. In September, Wallace tried to prevent the integration of public elementary and secondary schools in several cities. President Kennedy again called in the National Guard, and the black students were admitted. Since 1963, Alabama has gradually integrated most of its public schools. In March 1965, King led a five-day march from Selma to Montgomery to protest discrimination in voter registration. In August, Congress passed the Voting Rights Act, which made thousands of Alabama blacks eligible to vote.

Republicans gained increasing success in Alabama, a traditionally Democratic state. In 1964, Barry M. Goldwater became the first Republican presidential candidate to carry Alabama since 1872.

In 1960, the government established the George C. Marshall Space Flight Center at Huntsville. The Saturn 5 rocket system, which powered the first missions that landed astronauts on the moon, was developed at Huntsville during the 1960's.

Recent developments. Alabama, like other states, faced financial problems in the 1980's and early 1990's. The state government sought ways to provide sufficient funds for such services as state-supported nursing homes and public education. In 1980, the state legislature increased taxes on cigarettes and alcohol to increase funds for government services.

The rising costs of petroleum and natural gas have led to increased use of coal. This action has spurred further development of Alabama's coal deposits.

Industry continues to grow in the state, and the population has been rising steadily. African Americans are playing an increasingly important role in local and state politics. Republicans have also been gaining strength in local and state governments. In 1986, Guy Hunt became the first Republican to be elected governor of Alabama since Reconstruction. But he was removed from office in 1993, following his conviction for felony ethics violations. He was sentenced to pay fines and to perform 1,000 hours of community service. In 1998, Hunt was pardoned by a state parole board.

William D. Barnard and David C. Weaver

AP/Wide World

Martin Luther King, Jr., organized a boycott of the Montgomery bus system in 1955. Many blacks stopped riding buses because the law required them to sit in the rear. In 1956, a federal court ordered Montgomery to desegregate its buses.

Alabama, University of, is a coeducational state-supported educational system. Its official name is the University of Alabama System. It consists of three universities. The original campus is the University of Alabama in Tuscaloosa. The system includes the University of Alabama at Birmingham (UAB) and the University of Alabama in Huntsville (UAH). Each school offers bachelor's, master's, and doctor's degrees. The schools at Tuscaloosa and Birmingham have professional programs. The University of Alabama was founded in 1831. UAB and UAH were established as branches in the mid-1960's and began operating independently in 1969. In 1975, the system was established.

Critically reviewed by the University of Alabama

Alabama River flows through the East Gulf Coastal Plain of Alabama. It is formed where the Coosa and Tallapoosa rivers join north of Montgomery in the central part of the state (see Alabama [physical map]). The Alabama follows a winding course southwest for 315 miles (507 kilometers). At a point about 45 miles (72 kilometers) north of Mobile, it unites with the Tombigbee River to form the Mobile River.

The Alabama River is navigable for its entire length. Three dams lie along the river. They create three bodies of water—R. E. "Bob" Woodruff Lake, William Dannelly Reservoir, and Claiborne Lake. Power stations generated by the dams provide electric power. The lakes and reservoir are used for recreation. They also release water, as needed, to maintain a 9-foot (2.7-meter) navigation channel. Howard A. Clonts, Jr.

SCALA/Art Resource

An alabaster bust of King Tutankhamen dates back to the 1300's B.C. Many ancient Egyptian sculptors used alabaster.

Alabaster, *AL uh BAS tuhr,* is the name of two types of fine-grained white rocks that look similar but have different chemical compositions. Both types are used for ornamental purposes.

Today, the word *alabaster* commonly refers to a type of rock composed of the mineral gypsum. Gypsum is an extremely soft mineral made of calcium sulfate and water. Its chemical formula is $CaSO_4 \cdot 2H_2O$ and its crystals are *monoclinic* (see **Crystal** [Classifying crystals]). Craftworkers make vases, statues, and building stone from gypsum alabaster. It is soft, and workers can carve it without special tools. Deposits of this type of alabaster occur in many parts of the world.

The Metropolitan Museum of Art, New York City, Rogers Fund, 1926

An alabaster headrest was part of the rich furnishings of an ancient Egyptian tomb.

In ancient times, the word *alabaster* referred to a type of rock from which carvers made vases called *alabasters.* People kept ointments and perfumes in these vases. Carvers shaped alabasters from cave formations called *stalactites* and *stalagmites.* These formations are composed of calcite ($CaCO_3$), which is harder than gypsum. Calcite crystals are *hexagonal.* One kind of calcite alabaster, called *oriental alabaster,* is mined mainly near Florence, Italy. Another kind, *Egyptian alabaster,* was mined in ancient times near Thebes, Egypt.

Kenneth J. De Nault

Aladdin, *uh LAD uhn,* is the hero of one of the most famous tales of the *Thousand and One Nights,* also known as the *Arabian Nights.* His story is told by the Princess Scheherazade to her husband.

According to the tale, Aladdin is a poor Chinese boy who comes into the possession of a magic lamp. By rubbing the lamp, he can make a *genie* (spirit) appear who obeys Aladdin's every command. The boy becomes enormously rich and marries the sultan's daughter. But a magician plots against their happiness and tricks Aladdin's wife into giving up the lamp. Eventually, Aladdin regains the lamp, his prosperity, and his bride. When the sultan dies, Aladdin succeeds him. The charm of the story lies as much in Aladdin's humor and good will as in the description of fabulous events. Dick Davis

Alamein, El. See **El Alamein.**

Alamo, *AL uh moh,* is a historic structure in the center of San Antonio. A famous battle was fought there from Feb. 23 to March 6, 1836, during the war for Texan independence. The Alamo is sometimes called the *Thermopylae of America,* after the famous battle in which the ancient Greeks held off a large Persian force. No Texans escaped from the Alamo after the night of March 5. The Alamo is now a restored historic site.

Early days. The Alamo was built as a Roman Catholic mission. Padre Antonio Olivares, a Spanish missionary, established it at San Antonio in 1718. The mission consisted of a monastery and church enclosed by high walls. The mission was originally called *San Antonio de Valero.* It was later called *Alamo,* the Spanish name for the cottonwood trees surrounding the mission. The Texans occasionally used the mission as a fort.

During the winter of 1835-1836, the people of Texas decided to sever their relations with Mexico because of dissatisfaction with the Mexican government. To prevent the success of this independence movement, General Antonio López de Santa Anna, in command of the Mexican Army, approached San Antonio with his troops. Lieutenant Colonel William Barret Travis and a force of about 150 Texans sought to defend the city. The company included the famous frontiersmen James Bowie and Davy Crockett. The quick arrival of the Mexicans took the Texans by surprise. They retreated to the Alamo to hold off the Mexican force of approximately 4,000 troops. Travis sent out a plea for help, declaring, "I shall never surrender or retreat." A relief party from Gonzales, Texas, passed through the Mexican lines and entered the Alamo, increasing the Alamo forces to 189 men. Colonel J. W. Fannin left Goliad, Texas, with most of his 400 men to relieve the Alamo, but he had equipment trouble on the way and returned to Goliad.

The siege of the Alamo lasted 13 days. By March 5, the garrison could not return Mexican fire because ammunition was low. This convinced Santa Anna that the fort could be assaulted. Early the next morning, the Mexicans succeeded in scaling the walls. At the end, the Texans fought using their rifles as clubs. Some historians believe that a few defenders, perhaps including Crockett, survived the battle only to be executed at Santa Anna's orders. Other historians accept the more familiar story that all the Texans who fought died in the battle. At 8 a.m., the Mexican general reported his victory to his government. Survivors of the battle included Susanna Dickinson, the wife of an officer; her baby; her Mexican nurse; and Colonel Travis's black slave Joe.

The Battle of the Alamo took place in a mission in San Antonio. On the morning of March 6, 1836, Mexican troops under General Santa Anna successfully stormed the mission and killed all the defenders.

Dawn at the Alamo by H. A. McArdle, Texas State Library, Austin, Texas. WORLD BOOK photo by William Malone

"Remember the Alamo" became a battle cry. The determined defense of the Alamo gave General Sam Houston time to gather the forces he needed to save the independence movement of Texas. He retreated eastward, pursued by Santa Anna. At San Jacinto, Texas, he turned on the Mexicans, surprised them during an afternoon siesta, and on April 21, in just 18 minutes, captured or killed most of the Mexican army of over 1,200 men. Houston's army captured Santa Anna the following day and forced him to sign a treaty granting Texas its independence. Joseph A. Stout, Jr.

Alanbrooke, Lord (1883-1963), was one of Britain's military leaders during World War II (1939-1945). He won special distinction for his leadership during the retreat to—and, later, from—Dunkerque, France, after Belgium fell to Germany in May 1940. Alanbrooke served as chief of the Imperial General Staff from 1941 to 1946. He also fought in World War I (1914-1918).

Alanbrooke was born near Lourdes, France, of British parents. His given and family name was Alan Francis Brooke. In 1945, he became a nobleman and changed his name to Alanbrooke. Ian F. W. Beckett

Al-Anon, *AL uh nahn,* is a worldwide fellowship of the families and friends of alcoholics. Members learn that alcoholism is a disease and how it affects family life. They use this information to solve their own problems and to understand problem drinkers. Al-Anon has a teen-age division called Alateen.

Al-Anon cooperates with Alcoholics Anonymous (A.A.), an organization for alcoholics, but is not a branch of A.A. Al-Anon was incorporated in 1954. Its members, like A.A. members, use only their first names to ensure anonymity. Al-Anon groups work to follow A.A.'s 12 suggestions for better living, the Twelve Steps.

Al-Anon has about 500,000 members in more than 30,000 local groups. It collects no dues but accepts contributions from members to cover expenses. It is not connected with any religious or other group. Al-Anon's world service office, the Al-Anon Family Group Headquarters, Inc., is located in New York City.

Alarcón, *AH lahr KOHN,* **Pedro Antonio de** (1833-1891), was a Spanish author. He is best known today for his short novel *The Three-Cornered Hat* (1874), one of the most popular works in Spanish literature. In 1919, the Spanish composer Manuel de Falla adapted Alarcón's tale into a famous ballet of the same name.

Alarcón based *The Three-Cornered Hat* on a traditional Spanish ballad. His humorous story describes the confusion that occurs when a miller believes his wife has been having an affair with the mayor of the village. The story provides a lively picture of village life in Alarcón's native region of Andalusia. Alarcón wrote another popular short novel, *Captain Venom* (1881). One of his four novels, *The Scandal* (1875), became noted for its keen psychological insights. Alarcón also wrote travel books and short stories and essays.

Alarcón was born in Guadix, near Granada. In 1859, he served in a Spanish military operation in Morocco. He gained his first literary recognition with *A Witness' Diary of the African War* (1859-1860), a patriotic account of the campaign. David Thatcher Gies

Alaric, *AL uhr ihk* (A.D. 370?-410), was a king of the Visigoths. He invaded Italy and captured Rome in the early A.D. 400's. In 395, the declining Roman Empire split permanently into Eastern and Western empires. Alaric then led the Visigoths in a revolt against the Eastern Empire. He invaded Italy in 401, and began a series of attacks on the Western Empire. He attacked Rome in 408 and in 409, but accepted huge ransoms to end both sieges. In 410, he captured and looted Rome, but spared its churches. Alaric planned to settle in Africa, but a storm forced him to stop at Cosenza in southern Italy. He died there, late in 410. See also Goths. William G. Sinnigen

Mark Newman, Tom Stack & Assoc.

Mount McKinley, in central Alaska, has the highest summit in North America. Its South Peak rises 20,320 feet (6,194 meters) above sea level. Alaska's majestic mountains and vast areas of unspoiled wilderness attract many people who love the outdoors.

Alaska *The Last Frontier*

Alaska is the largest state of the United States in area. It is almost a fifth as large as all the rest of the United States, and more than twice the size of Texas, the second largest state. But Alaska has a relatively small population. According to the 2000 census, Alaska ranks 48th among all the states in population. Only Wyoming and Vermont have fewer people than Alaska. Alaska is often called the *Last Frontier* because much of the state is not fully settled. Juneau is Alaska's capital. Anchorage is the state's largest city in terms of population.

When Alaska entered the Union in 1959, it was the first new state in 47 years. About 500 miles (800 kilometers) of Canadian territory separate Alaska from Washington. Alaskans often refer to the rest of the continental United States as the "lower 48." The Alaska Highway, which runs between Delta Junction, Alaska, and Dawson Creek, British Columbia, Canada, connects Alaska with the road systems of the other states as well as with Canada.

The Alaskan mainland's most western point is only 51 miles (82 kilometers) from Russia. Alaska's Little Diomede Island, in the Bering Strait, is about 2 $\frac{1}{2}$ miles (4 kilometers) from Russia's Big Diomede Island. No other part of North America is closer to Asia.

Almost a third of Alaska lies north of the Arctic Circle. However, Point Barrow, the northernmost point, is almost 1,300 miles (2,090 kilometers) south of the North Pole. The state has a wide range of temperatures—as low as −80° F (−62° C), and as high as 100° F (38° C). The climate and soil as far north as the Arctic Circle permit farmers to raise livestock and grow barley, potatoes, and other crops. The summer sun shines about 20 hours a day in Alaska, and crops grow rapidly there. At Point Barrow, from May 10 to August 2, the sun never sets.

Alaska is famous for its towering mountains and beautiful scenery. Mount McKinley, which rises 20,320 feet (6,194 meters) above sea level, is the nation's highest peak. Alaska also has the 15 next highest peaks and almost all of the active volcanoes in the United States.

The contributors of this article are F. Patrick Fitzgerald, Professor of Geography and History at the University of Alaska Southeast at Juneau, and Claus-M. Naske, Executive Director, University of Alaska Press, and coauthor of Alaska: A History of the 49th State.

Interesting facts about Alaska

WORLD BOOK illustrations by Kevin Chadwick

Alaska has more inland water than any other state—20,171 square miles (52,243 square kilometers). Inland water covers an area in Alaska larger than the area of Vermont and New Hampshire combined.

The Aleutian islands of Attu and Kiska were the only parts of North America occupied by Japanese troops during World War II. The islands were captured in 1942 and recovered by the United States in 1943.

Japanese-occupied islands during World War II

Alaska has the longest general coastline of any state. It measures 6,640 miles (10,686 kilometers), a distance greater than that of all the other states' coastlines combined. The coastline of the Alaskan mainland and all the major islands washed by tidewater measures 33,904 miles (54,563 kilometers).

Bald eagles gather in greater numbers along the Chilkat River just north of Haines than at any other place in the world. Each year, more than 3,500 of the birds come to this site to feed on late runs of salmon. The salmon are accessible because an unusual upwelling of warm water keeps the river free of ice.

Bald eagles

Keith Gunnar, West Stock

Juneau, the capital of Alaska, is situated between steep mountains and a fine, deep harbor. In addition to government operations, the city's main industries are fishing, mining, and tourism.

Denali National Park, the site of Mount McKinley, is one of a number of national parks in the state. Wrangell-St. Elias National Park in Alaska is the nation's largest national park. It covers more than 8 million acres (3 million hectares). Alaska also has the nation's largest wildlife refuge. The Yukon Delta National Wildlife Refuge covers nearly 20 million acres (8 million hectares).

Inuits, Aleuts, and Indians were living in Alaska when Russian explorers arrived. A Russian trader established the first white settlement, on Kodiak Island, in 1784.

United States Secretary of State William H. Seward bought Alaska from Russia in 1867 for $7,200,000—only about 2 cents per acre (5 cents per hectare). Some Americans thought the region was a wasteland of ice and snow. They called it *Seward's Folly, Seward's Icebox,* and *Icebergia.* However, Alaska proved to be rich in fish, minerals, timber, and potential water power. The value of resources taken from the region has paid back the purchase price hundreds of times. Huge oil reserves at Prudhoe Bay along the Arctic coast rank as Alaska's chief source of wealth.

© Jane Gnass, West Stock

Downtown Anchorage includes a log cabin visitor information center, *shown here.* Anchorage is Alaska's largest city and the state's chief center of commerce and transportation.

Alaska in brief

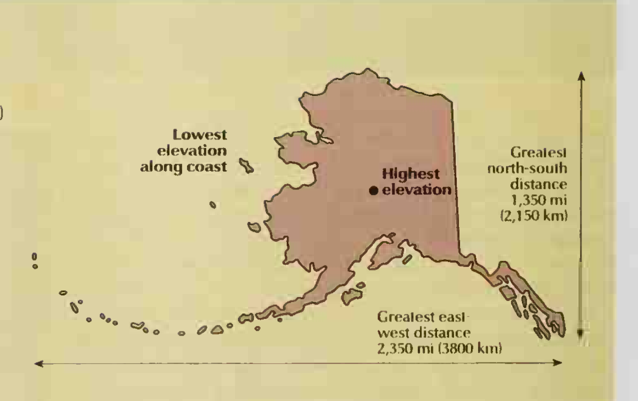
Symbols of Alaska

The state flag, adopted in 1927, was designed by a 13-year-old schoolboy. Seven gold stars, representing Alaska's gold resources, form the Big Dipper. An eighth star in the corner is the North Star, symbolizing Alaska's location in the Far North. The state seal was adopted in 1913. It has symbols, relating to Alaska's economy, for agriculture, fishing, forestry, mining, and transportation. The rays above the mountains represent the northern lights.

State flag

State seal

Alaska (brown) is the largest state in the United States.



The State Capitol is in Juneau, the capital of Alaska since 1900. Sitka served as capital from 1884 to 1900.

General information

Statehood: Jan. 3, 1959, the 49th state.
State abbreviation: AK (postal).
State motto: *North to the Future.*
State song: "Alaska's Flag." Words by Marie Drake; music by Elinor Dusenbury.

Land and climate

Area: 587,878 mi² (1,522,596 km²), including 17,502 mi² (45,329 km²) of inland water but excluding 27,355 mi² (70,848 km²) of coastal water.
Elevation: *Highest*—Mount McKinley, 20,320 ft (6,194 m) above sea level. *Lowest*—sea level.
Coastline: 6,640 mi (10,686 km).
Record high temperature: 100 °F (38 °C) at Fort Yukon on June 27, 1915.
Record low temperature: −80 °F (−62 °C) at Prospect Creek, near Stevens Village, on Jan. 23, 1971.
Average July temperature: 55 °F (13 °C).
Average January temperature: 5 °F (−13 °C).
Average yearly precipitation: 55 in (140 cm).

The state's official Web site at www.state.ak.us also provides a gateway to much information on Alaska's economy, government, and history.

1912 Congress established Alaska as a U.S. territory.
1959 Alaska became the 49th state on January 3.
1968 Large oil reserves were discovered near Prudhoe Bay.
1971 The Alaska Native Claims Settlement Act passed.
1977 The Trans-Alaska Pipeline was completed.
1980 Congress passed the Alaska National Interest Lands Conservation Act.
1989 Tanker in Prince William Sound caused largest oil spill in U.S. history.
1992 Most oil-spill cleanup completed at cost of more than $2 billion.

People

Population. The 2000 United States census reported that Alaska had 626,932 people. The population had increased 14 percent over the 1990 figure of 550,043. According to the 2000 census, Alaska ranks 48th in population among the 50 states. Only Wyoming and Vermont have fewer people than Alaska.

About a third of Alaska's people were born in Alaska. Many of those who were born in other states are members of the United States armed forces that are assigned to Alaska. Alaska has about 98,000 *natives.* Of this figure, about two-thirds are Inuit and one-third are Indians. Most Inuit live in the north and west. About 10,000 of the Inuit are Aleuts. Aleuts live on the Alaska Peninsula and the Aleutian Islands. Haida, Tlingit, and Tsimshian Indians live in the southeast. Athabaskan Indians live mainly in Alaska's interior.

Most of the white population lives in or near Anchorage, Alaska's largest city; in Fairbanks; and in the southeastern coastal cities. Anchorage is Alaska's only metropolitan area (see **Metropolitan area**).

Schools. The commissioner of education heads Alaska's education department. The commissioner is appointed by the State Board of Education and Early Development subject to the governor's approval. Seven voting members of the board are appointed by the state's governor. Two nonvoting members, representing students and the military, also sit on the board. The board establishes policies for Alaska's public school system.

Children in Alaska must attend school from the ages of 7 through 15. Each organized borough is a school district and has a school board. Cities that lie outside the organized boroughs have city school boards. Regional school boards operate schools in rural areas outside the organized boroughs.

Alaska has three schools that grant bachelor's or advanced degrees and are accredited by the Northwest Association of Schools and Colleges. The University of Alaska has several campuses throughout the state (see **Alaska, University of**). The state's two other colleges are Sheldon Jackson College in Sitka and Alaska Pacific University in Anchorage.

Libraries and museums. Alaska's State Library, in Juneau, includes a historical section and state archives and records management services section. Academic libraries are located at the University of Alaska Fairbanks, the University of Alaska Anchorage, and the University of Alaska Southeast in Juneau.

The Alaska State Museum in Juneau features exhibits of Inuit and Indian objects. It also has displays dealing with animals and minerals in the state. A branch of the state museum, the Sheldon Jackson Museum in Sitka, has Inuit and Indian collections. The University of Alaska Museum in Fairbanks focuses on the state's cultural and natural history. Other cities that have museums include Anchorage, Bethel, Haines, Homer, Kenai, Ketchikan, Kodiak, Nome, Palmer, Petersburg, Skagway, and Wasilla.

Population density

Alaska is the most thinly populated state. Most Alaskans live in Anchorage or along the southeastern coast. Anchorage is the state's largest city in terms of population.

WORLD BOOK map, based on U.S. Census Bureau data.

University of Alaska, Fairbanks

The University of Alaska has several campuses. The Gruening Building on the Fairbanks campus, *shown here,* was named for Ernest Gruening, known as "the father of Alaskan statehood." He was governor of the Alaska Territory from 1939 to 1953 and a U.S senator from the state from 1959 to 1969.

Visitor's guide

Alaska's vast wilderness attracts many people who love the outdoors. Expert mountain climbers tackle Alaskan peaks that rank as the highest in North America. People fish for record-sized salmon, trout, and halibut.

Thousands of tourists come to see Alaska's magnificent mountain scenery and historic coastal towns. Many vacationers from the "lower 48" drive to the state on the Alaska Highway or take a scenic cruise along the Inside Passage of Alaska's southeastern coast.

Alaska offers interesting activities for everyone. These activities include white water kayaking, bird watching, and photographic tours of the famous "northern lights."

Perhaps the most popular winter event in Alaska is the Iditarod Trail Sled Dog Race. Sled drivers called mushers and their teams of dogs race over a rugged course from Anchorage to Nome. Held each March, the course is about 1,200 miles (1,930 kilometers) long and usually takes about 12 days to complete.

Iditarod Trail Sled Dog Race between Anchorage and Nome

Places to visit

Following are brief descriptions of some of Alaska's many interesting places to visit.

Alaska Highway extends 1,397 miles (2,248 kilometers) between Dawson Creek, B.C., and Delta Junction. Linking highways go north to Fairbanks, in gold rush country, and south to Anchorage and other cities. See **Alaska Highway**.

"Marine Highway" is Alaska's state ferryliner system. Oceangoing ferryliners carry cars and passengers along this route from Prince Rupert, B.C., and Bellingham, Wash., to southeastern coastal cities. The ferryliners follow the Inside Passage running between forested islands and the steep, inlet-cut mainland coast. Each town located along this scenic route offers special attractions to visitors. Saxman, near Ketchikan, for example, has the world's largest collection of authentic Indian totem poles. Ketchikan also has a large collection of authentic totem poles. Sitka, which was the capital when Alaska belonged to Russia, includes historic St. Michael's Cathedral, a Russian Orthodox church. Juneau, the state capital, offers close-up views of the Mendenhall Glacier. Visitors to the glacier can hike nearby trails or raft down the Mendenhall River. The Haines Highway connects the northern end of the ferryliner route with the Alaska Highway. In south-central Alaska, ferryliners operate between Cordova and Kodiak, with stops at Valdez, Whittier, Seward, Homer, and Seldovia.

National parklands in Alaska include Denali National Park, which features the highest peak in North America, majestic Mount McKinley (20,320 feet, or 6,194 meters, above sea level). Alaska is also the site of Gates of the Arctic National Park, Glacier Bay National Park, Katmai National Park, Klondike Gold Rush National Historical Park, Sitka National Historical Park, and Wrangell-St. Elias National Park. For more information, see the map and tables in the *World Book* article on **National Park System**.

National forests. Alaska has two national forests. They are Chugach, along the southern central coast, and Tongass, along the southeastern coast.

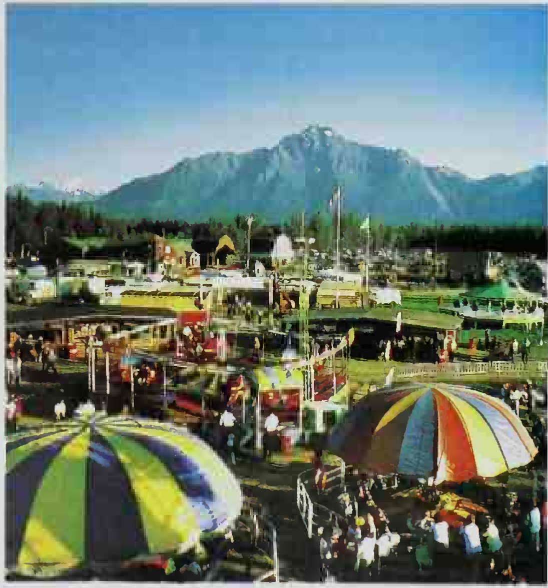
Annual events

January-June

Russian Christmas, in cities across the state (early January); Winter Sunrise in Barrow (late January); Fur Rendezvous in Anchorage (February); Iditarod Trail Sled Dog Race (March); Pillar Mountain Golf Classic in Kodiak (March); Alaska Folk Festival in Juneau (April); Jazz and Classics Festival in Juneau (May); Little Norway Festival in Petersburg (May); Kodiak Crab Festival (May); The Midnight Sun in Barrow (mid-May); Sitka Summer Music Festival (June).



July-December

World Eskimo-Indian Olympics in Fairbanks (July); State Fair in Palmer (August-September); Equinox Marathon Run in Fairbanks (September); Alaska Day Celebration in Sitka, commemorating the transfer of Alaska from Russia to the United States in 1867 (October); Athabascan Fiddling Festival in Fairbanks (November); Great Alaska Shootout in Anchorage, featuring college basketball teams from throughout the United States (November).

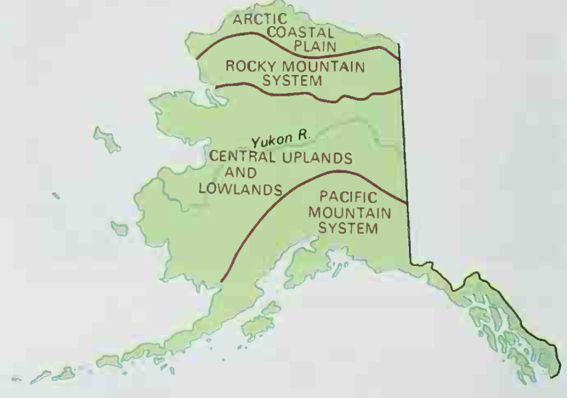
Land regions. Alaska has four main land regions: (1) the Pacific Mountain System, (2) the Central Uplands and Lowlands, (3) the Rocky Mountain System, and (4) the Arctic Coastal Plain.

The Pacific Mountain System of Alaska is part of a group of ranges that extends down the Pacific Coast to southern California. In Alaska, the ranges curve from the Aleutian Islands in the west through south-central Alaska and along the coast in the southeast.

The region has many subdivisions. The strip of coastal land 400 miles (640 kilometers) long in the southeast is called the Alaska Panhandle. It is 10 to 150 miles (16 to 241 kilometers) wide, and includes tall mountains and ice fields. The Saint Elias Range extends northwestward from the Panhandle. Mount Saint Elias rises 18,008 feet (5,489 meters) in this range. The Wrangell Mountains, northwest of the Saint Elias Range, include Mount Bona (16,421 feet, or 5,005 meters) and three tall peaks—Mount Blackburn (16,390 feet, or 4,996 meters), Mount Sanford (16,208 feet, or 4,940 meters), and Mount Wrangell (14,005 feet, or 4,269 meters). Mount Wrangell is an active volcano. The Chugach and Kenai mountains border the coast from the Saint Elias Range west to the Kenai Peninsula and Kodiak Island. Mount Fairweather, in the Chugach Mountains, is 15,300 feet (4,663 meters) high. The Talkeetna Mountains, north of Anchorage, are a low range of rugged, glacier-cut peaks. The Alaska Range is the most inland section of the Pacific Mountain System. From the Canadian border, it curves west and southwest to the Alaska Peninsula. The Alaska Range includes Mount McKinley (20,320 feet, or 6,194 meters), the highest peak in North America, and Mount Foraker (17,400 feet, or 5,304 meters).



The Alaska Peninsula and the Aleutian Islands extend southwest in a long chain from the Alaska Range. The Aleutians include 14 large islands, about 55 small islands, and many islets. The largest islands are Unimak, Unalaska, and Umnak. The Aleutian Range forms the "backbone" of the peninsula and islands. It extends 1,600 miles (2,570 kilometers), from Mount Spurr, across Cook Inlet from Anchorage, to Attu Island near the Asian con-

tinent. The range has many active volcanoes. The greatest eruptions occurred in 1912, at what is now Katmai National Park. A new volcano, Novarupta, hurled tons of rocks and ashes into the air. The top of Mount Katmai collapsed and formed a *caldera* (basin) 3 miles (5 kilometers) wide and 3,700 feet (1,130 meters) deep. The lava and ash from the volcano formed the Valley of Ten Thousand Smokes, an area of *fumaroles* (holes from which hot gas steams up).

Two important lowlands lie within the Pacific Mountain System. These are the Copper River Basin and the Susitna-Cook Inlet lowland. The Copper River Basin, a forested lowland with river canyons, extends between the Chugach and Wrangell mountains. During the Pleistocene Epoch, a time marked by a succession of ice ages, it was the site of a large lake. The most recent ice age ended about 11,500 years ago. The Susitna-Cook Inlet lowland extends north and east from Anchorage. Most of the area is forested. But it has a few towns and includes the fertile farmland of the Matanuska Valley.

The Central Uplands and Lowlands make up the largest Alaskan land region. This region lies between the Alaska Range on the south and the Brooks Range on the north. It extends westward from the Canadian border and includes the Seward Peninsula and the Kuskokwim River area of southwestern Alaska. The region has low, rolling hills. It also has broad, swampy river valleys, including the valleys of the Koyukuk, Kuskokwim, Tanana, and Yukon rivers.

The Rocky Mountain System of Alaska consists of the Brooks Range and its foothills. The Brooks Range has steep, glacier-cut peaks that rise to 9,000 feet (2,700 meters) in the east, but are lower in the west. It includes the Baird, De Long, and Endicott mountains.

The Arctic Coastal Plain is the most northern region. It rises gradually from the Arctic Ocean to a height of about 600 feet (180 meters) in the south. *Permafrost* (permanently frozen ground) 1,000 feet (300 meters) thick lies under the plain. No trees can grow there. But the surface of the ground thaws during summer and becomes thickly carpeted with low grasses and wild flowers. This grassy, treeless area is called the *tundra*.

Federally protected lands. Alaska includes 16 national wildlife refuges. These lands are part of the National Wildlife Refuge System, established by the U.S. government to protect and increase wildlife and their habitat. The system is managed by the U.S. Fish and Wildlife Service. Alaska's refuges make up more than 80 percent of the land in the system. The Yukon Delta National Wildlife Refuge, in western Alaska, ranks as the nation's largest refuge. It covers nearly 20 million acres (8 million hectares).

The Arctic National Wildlife Refuge, in northeastern Alaska, has become a topic of debate between environmentalists and the oil and gas industry. Oil companies have sought the right to drill for oil on the coastal plain in the northern part of the refuge. Environmentalists have protested that the drilling would damage the refuge. The federal government has not allowed drilling to take place. See **National Wildlife Refuge System.**

Coastline. Alaska's general coastline is 6,640 miles (10,686 kilometers) long. About 5,580 miles (8,980 kilometers) are along the Pacific Ocean, and about 1,060 miles (1,706 kilometers) are along the Arctic Ocean. All the coastline of the mainland and major islands washed by tidewater measures 33,904 miles (54,563 kilometers). The main features of the coast in the south are the Gulf of Alaska, Prince William Sound, and Cook Inlet. Bristol Bay and Norton Sound open into the Bering Sea in the southwest. Kotzebue Sound faces the Chukchi Sea in the northwest. The Arctic Ocean and the Beaufort Sea border the northern coast.

The southern coast is cut by hundreds of small bays, channels, and narrow, steep-sided inlets called *fiords*. The islands of the Alexander Archipelago rise from the Pacific off the shore of the Alaska Panhandle. Prince of Wales Island, the largest of the group, is the home of most of Alaska's Haida Indians. Ketchikan is on Revillagigedo Island, and Sitka is on Baranof Island. Other large islands in the group include Admiralty, Chichagof, and Kupreanof. Kodiak, Afognak, and several smaller islands lie southwest of the Kenai Peninsula in the Gulf of Alaska. The Pribilof Islands in the Bering Sea are the summer home of the world's largest fur seal herd. Nunivak Island, northeast of the Pribilofs, is the home of many musk oxen. Saint Lawrence Island is located at the southern end of the Bering Strait. Little Diomede Island and Big Diomede Island are located in the Bering Strait.

Artstreet

Mendenhall Glacier near Juneau fills a valley with ice and rock. This glacier is one of several in Alaska that can be reached by highway.

Little Diomede is part of Alaska. Big Diomede belongs to Russia.

Rivers and lakes. The Yukon River, Alaska's chief waterway, is the fifth-longest river in North America. It flows 1,979 miles (3,185 kilometers) through Alaska and parts of Canada. From June to October, the river is free of ice. Small boats and barges can travel from its mouth on the Bering Sea across Alaska and into Canada. The Yukon's main tributaries are the Koyukuk and the Tanana rivers. See **Yukon River**.

Alaska's second-longest river, the Kuskokwim, empties into the Bering Sea at Kuskokwim Bay. The Colville River flows into the Arctic Ocean, and the Noatak and Kobuk rivers flow into the Chukchi Sea at Kotzebue Sound. The Susitna and Matanuska rivers flow into Cook Inlet, and the Copper River empties into the Gulf of Alaska. Several rivers, including the Alsek, Stikine, and Taku, begin in Canada and flow south or west across the Alaska Panhandle to the Pacific.

Harold E. Wilson, Warden & Associates

Northern fur seals spend the summer on islands off Alaska's coast. The world's largest herd lives on the Pribilof Islands.

Alaska has thousands of lakes. The largest, Iliamna Lake on the Alaska Peninsula, is 80 miles (130 kilometers) long and 20 miles (32 kilometers) wide. Other lakes include Aleknagik, Becharof, Clark, Minchumina, Naknek, Selawik, Skilak, Teshekpuk, and Tustumena.

Glaciers. Thousands of glaciers from 1 to 30 miles (1.6 to 48 kilometers) long fill Alaska's mountain valleys and canyons. The greatest number of glaciers are along the coast in the south and southeast. Malaspina, in the Saint Elias Range, is North America's largest glacier. It is an ice sheet almost 50 miles (80 kilometers) wide. Many Alaska glaciers are easy to reach, and scientists from all parts of North America come to study them. Columbia Glacier can be reached by boat from Cordova. This huge ice sheet ends in an ice cliff in the sea. Glaciers that can be reached by highway include Black Rapids, Canwell, Castner, Gulkana, Matanuska, Mendenhall, Portage, and Worthington.

Plant and animal life. Forests cover about a third of

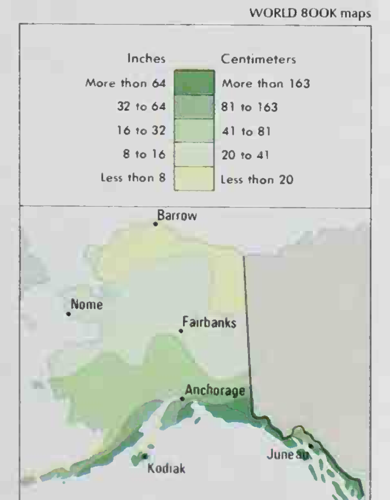
Average January temperatures

The southern coastal areas generally remain above freezing in winter. The rest of the state can be extremely cold.

Average July temperatures



Alaska has short, cool summers with big variations in temperature between the cold north and milder southern areas.

Average yearly precipitation

The southern coastal areas receive heavy precipitation. The rest of the state generally is extremely dry.

WORLD BOOK maps

Alaska. The most important trees are birches, Sitka spruces, western hemlocks, and white spruces. Other trees include aspens, black spruces, cottonwoods, tamaracks, and willows.

Grasses, mosses sedges, and plantlike organisms called lichens are found in many parts of Alaska. In the far north, they provide food for caribou and other animals. Wild flowers also grow throughout the state. Wild flowers on the tundra include asters, cinquefoils, fireweeds, forget-me-nots, larkspurs, and mountain laurels. Arctic daisies, bog laurels, cowslips, violets, wild hyacinths, and wood nymphs bloom in the mountains.

The waters off Alaska's shores are rich in salmon and halibut. They also contain great quantities of clams, cod, crabs, herring, and shrimp. The world's largest herd of fur seals is found on the Pribilof Islands in summer. A herd of musk oxen lives on Nunivak Island. Brown bears live on Kodiak Island and in other parts of south-central and southeast Alaska. Polar bears live along the Arctic Coast. Other animals include caribou, deer, elk, grizzly bears, moose, mountain goats, and mountain sheep. Game birds include ducks, geese, and grouse.

Climate. Alaska has a great variety of climates. Winds that blow eastward over the warm Kuroshio (Japan Current) give southern Alaska a fairly mild climate. Near the southern coast, temperatures average 28 °F (−2 °C) in January and 55 °F (13 °C) in July. *Precipitation* (rain, melted snow, and other moisture) averages 20 inches (51 centimeters) at Cook Inlet and 92 inches (234 centimeters) in the Panhandle. Parts of the southeast coast get heavy precipitation. Port Walter, on Baranof Island, has the highest average yearly precipitation in the continental United States—221 inches (561 centimeters).

In the inland parts of Alaska, temperatures average about −9 °F (−23 °C) in January, and about 59 °F (15 °C) in July. The annual precipitation averages about 13 inches (33 centimeters). Fort Yukon recorded Alaska's highest temperature, 100 °F (38 °C), on June 27, 1915. The record low, −80 °F (−62 °C), was set at Prospect Creek, near Stevens Village, on Jan. 23, 1971. This ranks as the lowest temperature ever recorded in the United States.

The Alaskan Arctic has an average January temperature of −11 °F (−24 °C). Its average July temperature is 47 °F (8 °C). Annual precipitation is very low.

Economy

Alaska's economy relies heavily on government activities and petroleum production. The huge amounts of petroleum produced by Alaska's oil industry are shipped to other states in oil tankers and through the Trans-Alaska Pipeline. While mining remains one of Alaska's most important economic activities, other industries have helped diversify the state's economy.

Service industries, which include such activities as government operations, transportation, and real estate, are also important to the state. Tourism benefits many businesses in Alaska, including hotels, shops, restaurants, and tour organizers. More than 1 million tourists visit the state annually, spending about $1 billion.

Fishing is the dominant industry in many parts of the state. Alaska catches more fish than any other state.

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Government	21	92,900	24
Transportation, communication, & utilities	18	29,900	8
Mining	15	11,900	3
Community, business, & personal services	13	104,400	27
Finance, insurance, & real estate	12	22,600	6
Wholesale & retail trade	10	70,900	19
Manufacturing	5	17,000	4
Construction	4	20,800	5
Agriculture, forestry, & fishing	2	14,500	4
Total	100	384,900	100

*GSP = gross state product, the total value of goods and services produced in a year.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

Mount Roberts Tramway is a popular tourist attraction in Juneau. It carries passengers to the top of Mount Roberts. Tourism contributes greatly to Alaska's economy.

Land use is a difficult problem in Alaska, as economic development and environmental protection interests often clash. The federal government owns and controls most of the state's land, and it has set aside large areas for wildlife conservation and national parklands.

Natural resources of Alaska include rich soils, valuable minerals, and plentiful water, fish, and forests.

Soil. Most interior valley soils in Alaska are composed of *loess* (coarse particles of dust deposited by the wind). These soils resemble the soils found in the western United States, China, and other highly productive farm areas. Although Alaska's soils are naturally productive, they need much fertilizer.

Minerals. Oil and natural gas have been found on the Kenai Peninsula and in Cook Inlet in south-central Alaska. Large reserves of oil and natural gas lie near Prudhoe Bay on the state's Arctic coast. Whether to tap these reserves has become a major source of debate. Some of these reserves lie beneath the Arctic National Wildlife Range, a key breeding ground for many of Alaska's wild creatures. Natural gas also has been found near Point Barrow in the Arctic Coastal Plain. Coal is found in the Kenai Peninsula, the Matanuska Valley, the Arctic Coastal Plain, and along the Healy and Yukon rivers.

Much of Alaska's gold is found in streambeds in the Yukon River Basin near Fairbanks and the Seward Peninsula near Nome. Gold also is found in combination with other precious metals in underground deposits on many islands in southeastern Alaska.

A major zinc deposit lies northwest of Kotzebue. One of the largest molybdenum deposits in the world is near Ketchikan. Widespread deposits of sand and gravel are a valuable resource for the construction industry. In addition, Alaska has deposits of antimony, chromite, copper, gemstones, granite, limestone, nickel, platinum, silver, and tungsten.

Service industries, taken together, account for the largest portion of Alaska's *gross state product*—the total value of goods and services produced in a state in a year. Most of the service industries are concentrated in the urban areas of the state.

Government services contribute more to the gross state product than any other service industry. Government services include the operation of public schools, public hospitals, and military bases. An extensive network of government services is necessary because the state's people are spread over a large area. The federal government controls much of the state's land. Military bases are located near Anchorage and Fairbanks.

Transportation, communication, and utilities form Alaska's second-ranked service industry in terms of the gross state product. Transportation is essential to Alaska's economy because the state lies far from major markets. Pipeline and shipping companies transport petroleum to processors. Ships also bring such essential goods as automobiles and groceries to Alaska from other states. Alaska's location between Asia and the continental United States has also helped make it an air freight transfer hub for such companies as FedEx and United Parcel Service. At Kodiak Island, the Alaska Aerospace Development Corporation created the nation's first privately operated rocket launch complex. Telephone companies are the biggest part of the communications sector. Utilities provide gas, electric, and water service. More information about transportation and communication appears later in this section.

Next among service industries in Alaska is community, business, and personal services. This industry consists of a wide variety of establishments, including private health care, hotels, law firms, engineering companies, and repair shops. Engineering companies involved in mining, construction, and aerospace technology are especially important.

Ranking fourth among Alaska's service industries is finance, insurance, and real estate. Anchorage is Alaska's chief financial center. The buying and selling of buildings and other property is the major real estate activity.

Wholesale and retail trade rank fifth among Alaska's service industries in terms of the gross state product. The wholesale trade of petroleum products, groceries, and motor vehicles is important in Alaska. Major types of retail businesses include automobile dealerships, food stores, and hardware stores.

Mining. Petroleum provides about 95 percent of Alaska's mining income. The Prudhoe Bay area is one of the world's major petroleum-producing regions. Prudhoe Bay also contains vast natural gas reserves. Petroleum is transported south from Prudhoe Bay by the Trans-Alaska Pipeline. Petroleum is also pumped from oil fields in the Kenai Peninsula-Cook Inlet area.

For many years, gold was Alaska's major mined product. Alaska is still an important gold-mining state. Most of the gold is obtained from *placer deposits*—particles of gold in streambeds—near Fairbanks and Nome.

Alaska's mines also produce major amounts of zinc and silver. The Red Dog Mine, near Kotzebue, is the largest zinc mine in the United States. Greens Creek Mine, near Juneau, is a leading producer of both zinc and silver. Alaska's other mined products include coal, crushed stone, lead, molybdenum, and sand and gravel.

Manufacturing. Goods manufactured in Alaska have a *value added by manufacture* of about $\$1\frac{1}{2}$ million a year. This figure represents the increase in value of raw materials after they become finished products.

Food processing is Alaska's leading manufacturing activity in terms of value added by manufacture. Fish products are the main source of food-processing income. Many coastal cities process salmon. The processing of crab, halibut, herring, pollock, sablefish, and other groundfish is also important to the economy of Alaska.

©Jeff Schultz, Alaska Stock Images

The Red Dog Mine, the largest zinc mine in the United States, is in northwestern Alaska, near Kotzebue. A truck hauls zinc from the mine, *above.* Zinc is an important mineral product of Alaska.

Petroleum products rank second in terms of value added. The Fairbanks and Kenai areas have large oil refineries. Refineries also operate at Prudhoe Bay.

Fishing industry. Alaska leads the states in the annual value of fish caught by the commercial fishing industry. The state has a yearly fish catch valued at about $1 $\frac{1}{4}$ billion. Workers in the industry catch cod, flounder, groundfish, halibut, pollock, rockfish, sablefish, salmon, and smelt. Dungeness crab, king crab, scallops, sea urchins, shrimp, and tanner crab (also known as snow crab) are also harvested, as are herring eggs. Kodiak and Unalaska/Dutch Harbor are the chief fishing ports.

Forestry is an important component of Alaska's economy. Forest products exports top $200 million each year. Alaska has over 25 million acres (10 million hectares) of commercial forestland. The southern Panhandle has many log-processing camps and sawmills.

Agriculture. Farms cover well under 1 percent of Alaska's land area—only 880,000 acres (356,000 hectares). The fertile Matanuska Valley northeast of Anchorage produces about three-fourths of Alaska's farm products. Alaska has about 550 farms.

Milk is Alaska's most valuable livestock product, followed by eggs and beef cattle. Alaskan farmers also raise chickens, hogs, sheep, and lambs. Inuit keep herds of reindeer as a source of meat and hides.

The growing season in Alaska is very short. However, the summer sun shines about 20 hours a day in the central part of the state, and crops ripen quickly there. All fruits and vegetables that grow in a cool climate can be raised in Alaska as far north as the Arctic Circle. Greenhouse and nursery products are the leading source of agricultural income in Alaska. In addition, Alaskan farmers grow such crops as barley, hay, oats, and potatoes. Timber is also important in the state.

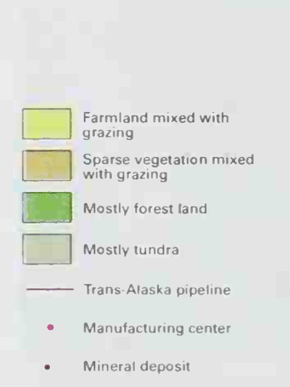
Fur industry. Alaska trappers catch many kinds of fur-bearing animals, including beavers, lynxes, martens, minks, wolves, and wolverines. The yearly value of the animals' pelts ranges from $5 million to $10 million.

Many Alaskans, most of them natives, hunt and fish for food. They also use animal skins in making clothing and other items for daily living.

Electric power. Power plants that burn natural gas provide about 55 percent of the electric power generated in Alaska. Hydroelectric plants generate about 25 percent of the state's power. Only a small fraction of the state's potential hydroelectric power has been developed. The rest of the state's power comes from coal-burning and petroleum-burning plants.

Transportation. It is difficult and expensive to build roads and railroads in Alaska. The land is rugged, and the construction season is short.

During World War II (1939-1945), the federal government built the Alaska Highway—the only major land route between Alaska, Canada, and the "lower 48." The highway extends between Dawson Creek, British Columbia, and Delta Junction, where it joins the Richardson Highway to Fairbanks. The Alaska Highway, together with the Richardson Highway, extends 1,495 miles (2,405 kilometers). Alaska has about 13,000 miles (20,900 kilometers) of roads and highways. Most of the state's roads link the Alaska Highway with the Kenai Peninsula, Anchorage, Valdez, and Fairbanks.



The state-owned Alaska Railroad provides freight service from Seward and Whittier to Anchorage and Fairbanks. This railroad also operates passenger trains.

Small planes flown by "bush pilots" provide the primary link between about 200 remote villages and the outside world. These pilots carry passengers, supplies, and mail across thousands of miles of rugged, remote country. Anchorage is a major air terminal. It serves as one of the world's busiest cargo hubs. Other major airports are at Juneau and Fairbanks.

Alaska depends on container ship service for most of

Economy of Alaska

This map shows the economic uses of land in Alaska and where the state's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

its trade with the "lower 48." The state's chief ports include Anchorage, Seward, Unalaska/Dutch Harbor, Valdez, and ports near Ketchikan and Kodiak. Nome, the main port on the Bering Sea, is blocked by ice in winter.

Alaska has an outstanding ferryliner system owned by the state. Three main routes serve coastal areas. In the southeast, huge ferryliners, each carrying as many as 108 cars, stop at several cities between Haines and Skagway in the north and Bellingham, Washington, and Prince Rupert, British Columbia, in the south. The Kodiak Island Ferry connects Seward, Kodiak, Homer, Valdez, and Cordova. The Prince William Sound ferryliner service links Valdez, Cordova, and Whittier.

Communication. The first public newspaper in Alaska, the *Sitka Times,* began publication in Sitka in 1868. Today, Alaska has about 35 newspapers, of which 6 are dailies. The leading daily newspapers published in Alaska include the *Anchorage Daily News, Fairbanks Daily News-Miner,* and *Juneau Empire.*

The first radio station in Alaska, KFQD, started broadcasting from Anchorage in 1924. The state's first television stations, KTVA-TV and KFIA-TV (now KENI-TV), began operating in 1953, also in Anchorage. Today, the state has about 75 radio stations and 15 television stations. Cable television systems and Internet providers serve most of Alaska's communities.

Government

Constitution. Alaska's present Constitution was adopted in 1956, three years before the territory became a state. A constitutional amendment must be approved by two-thirds of the members of each house of the state legislature. Then it must be approved by a majority of voters in a statewide election.

Amendments may also be proposed by a constitutional convention. The convention must be approved by a majority of each house of the legislature. It must then be approved by a majority of the people who vote on the issue in an election. All amendments proposed by the convention must be approved by the voters. If no convention has been held in a 10-year period, the question of calling a convention must be put to the voters.

Executive. The governor of Alaska is elected to a four-year term and cannot serve more than two terms in a row. Alaska's lieutenant governor is the only other elected state official. He or she is elected to a four-year term and can be reelected any number of times.

The state's other top executive officials include 13 commissioners, each of whom heads one of Alaska's 15 executive departments. Alaska also has an attorney general, who heads the Department of Law, and an adjutant general, who heads the Department of Military and Veterans Affairs. The governor appoints these two officials and the 13 commissioners with the approval of a majority of the legislators voting in a joint session.

Legislature consists of a 20-member Senate and a 40-member House of Representatives. One senator is elected from each senatorial district. Each representative district elects one representative. Each senator serves a four-year term. Each representative serves a two-year term.

The legislature holds a regular session every year. The sessions begin on the second Monday in January, except in years following gubernatorial elections—when they begin on the third Monday in January. The length of the sessions is limited to 120 days. The legislature or governor may call a 30-day special session.

Courts. The highest court in Alaska is the state Supreme Court. It has five justices, one of whom is chosen by the other justices to serve a three-year term as chief justice. The Supreme Court concentrates on civil matters but has ultimate authority in all cases.

The Court of Appeals, which has three judges, is the second-highest court for criminal matters. The Superior Court, Alaska's second-highest court for civil cases, has 32 judges. It is divided into four districts. District courts handle some civil and criminal cases. Seventeen district court judges serve in Alaska's four judicial districts. The Court of Appeals has jurisdiction to review district court decisions.

The governor appoints the Supreme Court justices and the Superior Court and Court of Appeals judges from people nominated by the Alaska Judicial Council. This council consists of the chief justice and six private citizens. After serving three years, a Supreme Court justice or Superior Court or Court of Appeals judge must be approved by the voters in the next general election. Each Supreme Court justice must be reapproved every 10 years. Superior Court judges must be reapproved every 6 years, and Court of Appeals judges every 8 years.

The governor appoints district court judges from candidates recommended by the Alaska Judicial Council. Voters must approve such judges in the first general election held more than two years after their appointment, and every four years thereafter.

Local government. Alaska is divided into 16 local government units called *organized boroughs*. Organized boroughs are incorporated areas that may include cities, suburbs, and rural areas. They are equivalent to counties in other states. Each borough is governed by an assembly of from 5 to 11 members. In most boroughs, the top administrative officer is a mayor elected by the people. A borough may instead have a manager appointed by the assembly. Other borough officials are appointed by the mayor or the manager. Organized boroughs cover only about 44 percent of Alaska. However, they have about 85 percent of the population. The rest of the state is called the *unorganized borough*. It is governed by the Legislature.

Alaska's cities use a mayor-council or city-manager form of government. All of the cities have elected city councils.

Revenue. Much of the income of Alaska's government comes directly from oil and gas production. Petroleum companies pay the state production taxes and *royalties,* a share of their profits. In addition, the state receives revenue from taxes on corporate income, motor fuels, and property. Alaska also gets money from federal grants and other U.S. government programs. The state has no personal income tax or sales tax.

Politics. Fewer contests take place between political parties in Alaska than in most other states. Almost all of Alaska's state and local government officials are appointed or are elected on a *nonpartisan* (no-party) basis. The state's elections for governor have resulted in several victories for both Democrats and Republicans. In elections for president, Alaska's voters have favored the Republican candidate almost every time. For Alaska's electoral votes and voting record in presidential elections, see Electoral College (table).

The governors of Alaska

	Party	Term
William A. Egan	Democratic	1959-1966
Walter J. Hickel	Republican	1966-1969

Tony Knowles	Democratic	1994-

History

Early days. No one knows exactly how long human beings have lived in America. But most scientists believe that the first Americans walked across a land bridge from Asia into what is now Alaska about 15,000 years ago. In the 1700's, when whites first arrived in the Alaskan region, three groups of people—Inuit, Aleuts, and Indians—were living there.

The Inuit lived in the Far North and West. From Alaska's north coast to Greenland, Inuit hunted such large sea mammals as whales, seals, and polar bears. Some small groups of Inuit inhabited inland areas and hunted caribou.

The Aleuts, closely related to the Inuit, lived on the Aleutian Islands and the Alaska Peninsula. The Aleuts were skillful sea hunters.

The largest Indian groups, the Tlingit and Haida, lived along the coast, where fish and game were plentiful. Some Tsimshian Indians also lived there. The Athabaskan Indians lived in the interior, a rugged region without the rich natural resources of the coast. The Athabaskans fished and hunted caribou.

European exploration. The Russians were the first Europeans to become interested in the Alaskan region. In 1648, a group of Russians, led by Semen I. Dezhnev,

Anchorage Museum of History and Art

Totem poles carved by the Haida Indians stand at Kasaan, on Prince of Wales Island. Totem poles are a traditional Indian art form in the Pacific Northwest. They symbolize tribes or families.

sailed through the strait separating northeastern Asia and northwestern North America. In 1725, Czar Peter the Great of Russia commissioned Vitus Bering, a Danish navigator, to explore the North Pacific region. Bering and his crew traveled more than 6,000 miles (9,700 kilometers) across Russia and Asia. Then they built a ship and in 1728 sailed through the strait navigated earlier by Dezhnev. This body of water later became known as the Bering Strait. But Bering did not sight the North American mainland because of fog.

In 1741, Bering and Aleksei Chirikov, a Russian explorer, led a second expedition to the region. Bering's party sighted Mount St. Elias in southeastern Alaska and landed on what is now Kayak Island.

Expeditions from England, France, and Spain soon reached Alaskan waters. Most of these explorers sought a sea route between the Atlantic and Pacific oceans.

The Russian era. Members of the second Bering expedition returned to Russia with sea otter furs. Russian traders and hunters then developed a brisk fur trade on the Aleutian Islands and later on the mainland. Fur traders enslaved the Aleuts and, by overhunting, nearly destroyed populations of fur-bearing animals in the Aleutians. In 1784, Gregory Shelikof, a trader, established the first white settlement in Alaska, then called *Russian America,* on Kodiak Island.

In 1799, Russia chartered the Russian-American Company, a trading firm. Alexander Baranof became the firm's chief manager. Baranof moved the company's headquarters to Novo Arkhangelsk (New Archangel, now Sitka), which he captured from the Tlingit Indians. Novo Arkhangelsk became the largest town in Russian America. Baranof managed company affairs profitably for the stockholders, and he established good relations with many native groups. The Russian-American Company sent Russian Orthodox priests to convert the native Alaskans to Christianity.

In 1818, Baranof retired, and the company began to lose money. Russian naval commanders then ruled the colony.

In 1824 and 1825, Russia signed separate treaties with the United States and Great Britain. These pacts recognized latitude 54°40′ as the southern boundary of Russian territory in America. As part of the agreements, Russia gave the United States and Britain trading rights along Alaska's Pacific Coast.

American purchase. The Russians tried to develop several industries, including coal mining, shipbuilding, and whale hunting. But by the 1850's the fur trade had declined and the company's other enterprises had begun to fail. After the Crimean War (1853-1856) weakened Russia, the country became eager to sell Alaska. United States Secretary of State William H. Seward agreed to buy the region for $7,200,000, about 2 cents per acre (5 cents per hectare). On March 30, 1867, he signed the Treaty of Cession of Russian America to the United States. Some Americans opposed the purchase. They called Alaska such names as *Seward's Folly, Seward's Icebox,* and *Icebergia.* But many Americans favored the acquisition. Congress approved the purchase, and American troops raised the U.S. flag at Sitka on Oct. 18, 1867.

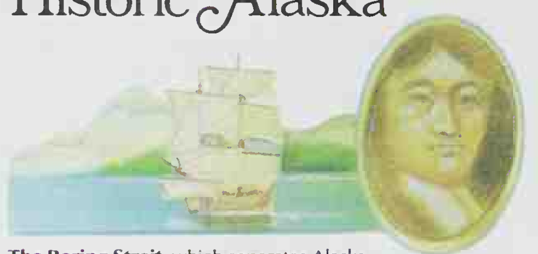
Congress did not provide for an Alaskan government during the next 17 years. Alaska was administered first by the War Department, next by the Treasury Department, and then by the Navy Department. These three agencies had little interest in the local problems of the region.

A few American companies became interested in Alaska's rich salmon fisheries. In 1878, they built the first canneries in Alaska.

In 1884, Congress passed the first Organic Act. This act established Alaska as a "civil and judicial district." It provided for a governor, a code of laws, and a federal court. But the laws were the laws of Oregon, and they were not adapted to Alaskan conditions. Congress kept the power to make laws for Alaska.

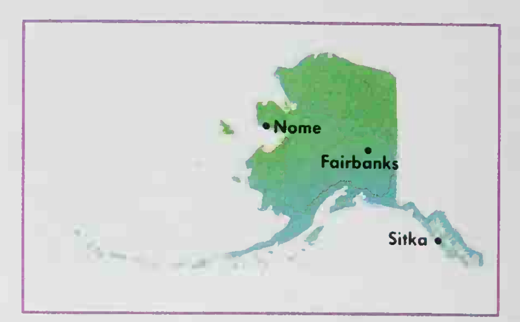
The gold rush. In 1880, Joseph Juneau and Richard T. Harris discovered gold deposits along Gastineau Channel in southeastern Alaska. This discovery led to the founding of the city of Juneau. In 1896, prospectors found rich gold deposits in the Klondike district of Canada's Yukon region, just across the border from Alaska. The discovery led to the Klondike and Alaska gold rush of 1897-1898. Miners discovered gold at what is now Nome in 1898 and in the Fairbanks area in 1902. The three gold discoveries attracted thousands of people hoping to strike it rich and aroused nationwide interest in Alaska. Alaska's population nearly doubled in 10 years, reaching 63,592 by 1900.

The early 1900's. The gold discoveries focused congressional attention on Alaska. In 1903, a group of U.S. senators toured the territory to learn of Alaska's needs. They recommended that the government construct a system of transportation routes there. Congress then created a Board of Road Commissioners for Alaska, which built and maintained wagon roads, trails, bridges, and ferries throughout the territory.



In 1906, Congress allowed Alaskans to elect their own delegate to Congress. They chose Frank H. Waskey, a Democrat. He could speak in the House of Representatives but was not allowed to vote. During this period, James W. Wickersham, a federal judge, rallied Alaskans to the cause of more self-government for Alaska. In 1908, Wickersham was elected Alaska's delegate to Congress. In 1912, Congress passed the second Organic Act, which gave Alaska a territorial legislature with limited powers.

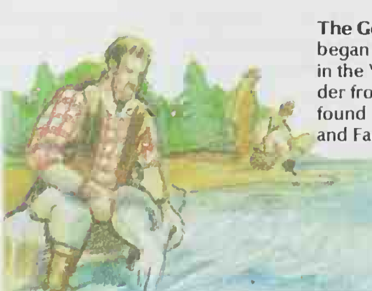
The Alaska Native Brotherhood (ANB) was formed in 1913. It was joined by the Alaska Native Sisterhood two years later. These organizations sought to unite the native communities of the region and fought for the political interests of its members. The groups helped achieve voting rights, integrated classrooms, and other civil rights for Alaska's native peoples.



In 1929, the ANB enlisted Wickersham to pursue a settlement for native lands seized by the federal government. Wickersham failed to persuade Congress to recognize native land claims. But the work of his successors and native groups eventually led to the Alaska Native Claims Settlement Act of 1971.

World War II (1939-1945) caused great changes in Alaska. The United States recognized the military importance of the territory, which lay close to Asia, and sent thousands of workers there to build and maintain military installations. In 1942, the Japanese bombed Dutch Harbor in the Aleutian Islands and occupied Kiska and Attu, two islands in the chain. These islands were the

Historic Alaska



The Bering Strait, which separates Alaska from Russia, was named after Danish navigator Captain Vitus Bering, who explored the waters around Alaska in the early 1700's.

The U.S. bought Alaska from Russia in 1867. Secretary of State William H. Seward paid $7,200,000 for the region.

The Gold Rush of 1897 and 1898 began after the discovery of gold in the Yukon, just across the border from Alaska. Gold was later found near what are now Nome and Fairbanks.

The Alaska National Interest Lands Conservation Act of 1980 set aside about 104 million acres (42 million hectares) as national parks, wildlife refuges, and other conservation areas.

The Russian-American Company, chartered in 1799, prospered in the fur trade under Alexander Baranof, its first manager. The company was based in what is today Sitka.

Important dates in Alaska

1741 The second Vitus Bering expedition landed on what is now Kayak Island.

1784 Russians established the first white settlement in Alaska, on Kodiak Island.

1824-1825 Russia agreed to recognize latitude 54°40′ as the southern boundary of Alaska.

1867 The United States purchased Alaska from Russia.

1884 Congress gave Alaska laws and a federal court.

1897-1898 The Klondike and Alaska gold rush started.

1906 Alaskans elected their first delegate to the U.S. Congress.

1912 Congress established Alaska as a U.S. territory.

1942 The Japanese bombed Dutch Harbor and invaded the Aleutians. The Alaska Highway was completed.

1958 Congress approved Alaskan statehood on June 30.

1959 Alaska became the 49th state on January 3.

1968 Large oil reserves were discovered near Prudhoe Bay.

1971 Congress passed the Alaska Native Claims Settlement Act, giving 44 million acres (18 million hectares) of land to native Alaskans.

1977 Workers completed construction of a pipeline to carry oil from Prudhoe Bay to Valdez.

1980 Congress passed the Alaska National Interest Lands Conservation Act, which placed about a fourth of the state's land in the National Park System.

1989 The *Exxon Valdez* dumped nearly 11 million gallons (42 million liters) of oil into Prince William Sound in the largest oil spill in United States history.

1992 Most of the *Exxon Valdez* oil-spill cleanup was completed at a cost of more than $2 billion.

National Archives

A U.S. Treasury warrant for $7,200,000 was used to purchase Alaska from Russia in 1867. The price came to about 2 cents per acre (5 cents per hectare).

only part of North America invaded during World War II. The government built the Alaska Highway in 1942, mainly as a military supply road. In 1943, about 152,000 military personnel were stationed in Alaska. United States troops recovered Kiska and Attu later that year, and the war in Alaska ended. But the military impact altered the territory forever.

Statehood. The war led to demands that Congress admit the territory to statehood. The first Alaskan statehood bill was introduced in Congress in 1916, but it did not receive a hearing. Other statehood bills were introduced from the mid-1940's until 1958. In 1958, Congress voted to admit Alaska to the Union. On Jan. 3, 1959, President Dwight D. Eisenhower signed the proclamation declaring Alaska the 49th state. Alaska became the first new state since 1912. William A. Egan, a Democrat, became the first elected governor of Alaska.

Alaska found its first years of statehood difficult and costly. It had to take over the expenses of public services that the federal government had provided. Congress helped by giving Alaska some buildings, transition grants, and other funding. Alaska also received funds from the lease of public lands and the right to claim 103.5 million acres (41.9 million hectares) of federal land over a 25-year period. State selection of lands began soon afterward. Alaska's Inuit and Indians, however, protested the selection process. They charged that the process did not recognize their claims of ownership or their traditional way of life, in which small bands moved over large areas hunting, fishing, and gathering food. These and other issues spurred the formation of the Alaska Federation of Natives (AFN) in 1966. The organization included representatives from nearly every group of native people and helped lead the fight for a full set-

Marshal Lockman, Black Star

A massive earthquake rocked Alaska on March 27, 1964. In Anchorage, the city hit hardest by the quake, buildings crumbled and pavement fell 30 feet (9 meters) in a few seconds. The earthquake was one of the most powerful ever recorded on the North American continent.

Terry Domico, Earth Images

Construction of the Trans-Alaska Pipeline began in 1974 and was completed in 1977. The pipeline carries oil from Prudhoe Bay to the port of Valdez, a distance of about 800 miles (1,300 kilometers). It cost about $8 billion to build.

tlement of Alaska native land claims.

During the 1960's, the state improved its transportation facilities. It developed a state ferry system, the "Marine Highway," to serve coastal cities.

In 1964, one of the biggest earthquakes ever known to hit North America shook the area around Anchorage and Valdez. It measured 8.3 on the Richter scale. The quake and *tsunamis* (huge, destructive waves) that it caused killed 131 people and resulted in more than $400 million in property damage.

The discovery of oil. In 1968, the Atlantic Richfield Company announced the discovery of a giant oil field at Prudhoe Bay on the Arctic Coastal Plain. It was one of the greatest oil discoveries in history. This oil field has the largest reserves of oil in North America. In 1969, Alaska auctioned oil and gas leases on the field's 450,000 acres (182,000 hectares) and earned over $900 million. Construction of a pipeline to carry oil about 800 miles (1,300 kilometers) across the state, from Prudhoe Bay to the port of Valdez, began in 1974. The pipeline was completed in 1977 at a total cost of about $8 billion, and oil production began.

The development of the Prudhoe Bay oil field provided new jobs and greatly increased state revenues during the late 1970's and early 1980's. In 1976, Alaska's voters had approved an amendment to the state Constitution that created the Alaska Permanent Fund, a savings account that belongs to all the people of Alaska. The amendment calls for at least 25 percent of all money earned by mineral development to be deposited into this fund. In 1980, the high revenues created by the oil boom enabled the state government to abolish individual state income taxes. In 1982, every Alaskan resident of six months or more began receiving dividend payments from the Alaska Permanent Fund. Each year, 50 percent of the fund's earnings, averaged over a 5-year period, are distributed equally to eligible Alaskans.

Land-use issues. From 1971 to 1980, the federal government set aside large amounts of land for native Alaskans and for conservation purposes. In 1971, President Richard M. Nixon signed the Alaska Native Claims Settlement Act. This revolutionary measure gave $962.5 million and about 44 million acres (18 million hectares) of land to the state's Inuit and Indians. The act created 12 regional corporations to administer the money and the land. A 13th corporation was added later. Every Alaskan Inuit and Indian received shares in the corporations.

In 1978, 56 million acres (23 million hectares) of Alaskan land were set aside as national monuments. In 1980, Congress passed the Alaska National Interest Lands Conservation Act. This act added more than 104 million acres (42 million hectares) to the conservation system in Alaska. The measure established the boundaries for a widespread network of federal, state, native, and private lands.

The 1980 conservation act gave rural Alaskans priority in hunting and fishing for food on federal lands. Many urban Alaskans who hunt and fish for sport complained that these provisions discriminated against them. Disputes over hunting and fishing rights led to increasing racial tensions between urban whites and rural native people. During the 1990's, when Alaskans still failed to comply with the provisions of the act, the federal government took over fish and game management on these lands.

Recent developments. In 1989, an oil tanker, the *Exxon Valdez,* struck a reef in Prince William Sound in southeastern Alaska, causing the largest oil spill in United States history. Nearly 11 million gallons (42 million liters) of crude oil spilled into the sound. The oil polluted beaches and fishing waters and destroyed wildlife. Most of the cleanup work at the sound was completed in 1992 at a cost of more than $2 billion. But scientists continue to work toward restoring the ecological balance of the area. In 1998, the Alaska SeaLife Center opened in Seward, Alaska. Much of the center's construction was funded by money from a settlement in the *Exxon Valdez* case.

Alaska, University of, is a state-supported system of higher education. The system includes three multicampus universities, one community college, and a network of services for rural Alaska. The multicampus universities offer developmental, vocational, certificate, associate, undergraduate, and graduate degree programs. These schools are the University of Alaska Anchorage, which includes Kenai Peninsula College, Kodiak College, Matanuska-Susitna College, and Prince William Sound Community College; the University of Alaska Fairbanks, with campuses in Bethel, Dillingham, Fairbanks, Kotzebue, and Nome; and the University of Alaska Southeast, with campuses in Juneau, Ketchikan, and Sitka. The university was founded in 1917 in Fairbanks.

Critically reviewed by the University of Alaska

Alaska Highway is a 1,397-mile (2,248-kilometer) road that runs between Dawson Creek, British Columbia, and Delta Junction, Alaska. The Richardson Highway links Delta Junction and nearby Fairbanks. The Alaska Highway is the only highway that connects Alaska with the road systems of the other states and Canada.

United States Army engineers and civilian contractors built the Alaska Highway as a military supply route in 1942 and 1943, when the United States was fighting in World War II. The highway was originally known as the Alcan Highway. The highway's original length was 1,422 miles (2,288 kilometers). The southern 1,221 miles (1,965 kilometers) of the road that crosses Canada became the property of Canada on April 1, 1946. Reconstruction has shortened the length in Canada to 1,196 miles (1,925 kilometers). Some of the highway has a gravel surface, but most of it now has a higher grade of pavement.

John C. Hudson

Alaskan malamute is a strong, rugged sled dog that came originally from Alaska. The dog is large and compactly built, and its thick coat usually is wolf-gray or black and white, with darker markings on the head. The malamute carries its bushy tail over its back. When it sleeps, the Alaskan malamute curls up so that its tail covers its nose. Most malamutes weigh from 75 to 85 pounds (34 to 39 kilograms). A group of Inuit people called Malemiuts developed the breed. The Inuit are also known as Eskimos. See also Dog (picture: Working dogs); Sled dog. Critically reviewed by the American Kennel Club

Al-Azhar University is one of the oldest universities in the world. The university was founded about A.D. 970 in Cairo, Egypt, and is a center of Islamic learning. Al-Azhar University offers courses in Islamic theology, Islamic law, Arabic studies, medicine, engineering, and agriculture. About 90,000 students attend the university, which has two major campuses in the Cairo area and four campuses in other cities of Egypt. P. A. McGinley

Alba, *AL buh* or *AHL bah,* **Duke of** (1508?-1582?), also called the Duke of Alva, was a Spanish general and diplomat who served Kings Charles I and Philip II of Spain. In 1567, Philip made Alba governor of the Netherlands and ordered him to crush a revolt that had broken out there against Spain. Alba's court sentenced about 1,200 rebels to death and was called the Council of Blood. His brutality and harsh taxes only made Netherlanders more determined to be free. Patriots seized the major coast towns and attacked Spanish shipping. They cut the dikes, and the floodwaters stopped Alba's army. Alba returned to Spain in disgrace. But in 1580, he helped Philip conquer Portugal. The duke's full name was Fernando Alvarez de Toledo. Carla Rahn Phillips and William D. Phillips, Jr.

Albacore. See Tuna.

Albania is a small, mountainous nation in the Balkan Peninsula of southeastern Europe. It is one of the least developed countries in Europe. Most of the people make their living through agriculture.

Albania's name in Albanian, the official language, is *Shqipëria,* which means *The Land of the Eagle.* The country's full, official name is Republika e Shqipërisë (Republic of Albania). Tiranë is its capital and largest city.

Albania was part of the Ottoman Empire for over 400 years. It gained its independence in 1912. From 1944 until the early 1990's, Albania was a Communist country.

Government. A president serves as the head of state in Albania and is the nation's most powerful official. A prime minister serves as head of government and presides over a cabinet, which helps carry out the functions of the government.

WORLD BOOK maps

Albania's parliament, which is called the National Assembly, has one house of 140 members. The National Assembly elects the president, who then appoints the prime minister and the cabinet. Members of the National Assembly are elected by the people to four-year terms.

The country is divided into 27 *rrethe* (districts). These districts are further divided into *qytete* (towns) and, in the rural areas, *fshatra të bashkuara* (united villages). A people's council governs each of Albania's districts, towns, and united villages.

People. Albanians are divided into two major groups—the Ghegs and the Tosks—according to which Albanian dialect they speak. Most of the Ghegs live north of the Shkumbin (also spelled Shkumbî) River, and most of the Tosks live south of the river. A few Greeks live in the regions that adjoin Greece.

Most of the people live on farms or in rural villages. A few Albanians along the Adriatic coast earn their living by fishing. There are only 12 cities in Albania that have populations of more than 20,000.

Living standards in Albania are extremely low compared with those of other European countries. The incomes of most Albanians are small, but health care, social services, and education are free. Bread, vegetables, and such dairy products as cheese and milk make up the daily diet of most of the people.

Many Albanians are Muslims. Others belong to Eastern Orthodox Churches, and some are Roman Catholics.

All of Albania's children must complete eight years of school. The University of Tiranë is the country's largest university. For Albania's literacy rate, see Literacy (Literacy rates for selected countries).

Land. Mountains cover most of Albania. The North Albanian Alps tower about 8,500 feet (2,590 meters) above sea level. Mount Korabit (9,026 feet, or 2,751 meters), in the northeastern part of the country, is Albania's highest point. A coastal plain lies along the Adriatic Sea. Scrub forests cover about 30 percent of the country.

Albania's major rivers, the Bunë, Drin, Shkumbin, and Vjosë, all empty into the Adriatic Sea. However, the Bunë is the only river that can be used for shipping. Albania shares Lake Scutari (also called Lake Skhodra) with Yugoslavia, Lake Ohrid with Macedonia, and Lake Prespa with Macedonia and Greece.

Along the Adriatic, the climate is mild, with hot, dry summers and rainy winters. The mountains have a mod-

Facts in brief

Capital: Tiranë.
Official language: Albanian.
Area: 11,100 mi^2 (28,748 km^2). *Greatest distances*—north-south, 215 mi (346 km); east-west, 90 mi (145 km). *Coastline*—175 mi (282 km).
Population: *Estimated 2002 population*—3,152,000; density, 284 per mi^2 (110 per km^2); distribution, 54 percent rural, 46 percent urban. *1989 census*—3,182,400.
Chief products: *Agriculture*—corn, potatoes, sugar beets, wheat. *Mining*—chromite, copper, petroleum. *Manufacturing*—cement, fertilizers, food products, textiles.

Money: *Basic unit*—lek. One hundred qindarka equal one lek.

erate climate. The country's average annual rainfall varies from 40 to 60 inches (100 to 150 centimeters).

Economy. The government owns many businesses in Albania, especially mines and large factories. But most farms and small businesses are privately owned.

Agriculture employs more Albanians than any other economic activity. The country's chief crops include corn, grapes, olives, potatoes, sugar beets, and wheat. Farmers also raise such livestock as cattle, goats, poultry, and sheep.

Albania is rich in mineral resources, and mining ranks as the country's leading industrial activity. Albania's mines produce chromite, copper, lignite, nickel, and other minerals. The country also produces natural gas and petroleum. Albania has relatively few factories. Its factory products include cement, fertilizers, food products, and textiles.

Albania's exports include chromite, copper ore, fruits and vegetables, nickel, and petroleum. Farm and industrial machinery and mining equipment are among its chief imports.

Buses, bicycles, and trains are common means of transportation in Albania. Private ownership of automobiles was illegal until 1991. Albania's railroad network connects Tiranë and Durrës—the country's chief port—with such important industrial centers as Elbasan, Fier, Shkodër, and Vlorë. A small airport outside Tiranë links Albania with several European countries.

History. About 300 B.C., the Illyrian kingdom covered much of what is now Albania. Greece also had colonies in Albania then, and Greek civilization influenced the Illyrians. In 167 B.C., Roman forces conquered the Illyrians and spread Roman civilization into Albania. When the Roman Empire split in A.D. 395, much of Albania became part of the Eastern Roman, or Byzantine, Empire. Between the 300's and 1000's, Goths, Bulgarians, Slavs, and Normans invaded Albania. Southern Albania was part of the Byzantine Empire until 1204. During the 1300's, much of Albania became part of the Serbian Empire.

Ottoman rule. The Albanians long resisted attempts by the Ottoman Empire to take over the country. The most distinguished leader against the Ottomans was Scanderbeg (also spelled Skanderbeg or Skënderbeg), who became Albania's national hero. After Scanderbeg's death in 1468, the Ottomans conquered Albania, and it became part of the Ottoman Empire. However, during more than 400 years of Ottoman rule, Albanian chiefs controlled most local matters. Many Albanians became Muslims during this period.

Independence. A number of local uprisings took place in Albania during the Ottoman rule, but a nationalist movement did not develop in the country until the 1800's. In 1878, a group of Albanian leaders organized the League of Prizren, which called for Albanian self-government within the Ottoman Empire. But Albania remained under Ottoman rule until 1912, when it gained independence during the First Balkan War. In 1913, the great European powers established Albania's borders, and the country became a self-governing principality. The European powers selected William of Wied, a German prince, as ruler. But he ruled for only a few months.

Austro-Hungarians, Italians, Serbs, and French occupied Albania during World War I (1914-1918). The Italians remained until 1920, when Albania insisted on its independence. Ahmed Beg Zogu seized power in 1925, proclaimed Albania a republic, and became the country's first president. In 1928, Zogu made himself King Zog I. He ruled until 1939.

World War II. Italy invaded Albania in April 1939 and made the nation part of the Italian Empire. World War II

Ferdinando Scianna, Magnum

Tiranë is Albania's largest city. It has been the country's capital since 1920. Tiranë's central district, *left,* has many modern stone buildings.

began later that year. When Italy surrendered to the Allies in 1943, during the war, German troops occupied Albania.

During World War II, there were three main resistance movements in Albania: (1) a nationalist movement called Balli Kombetar, led by Midhat Frashëri; (2) a royalist group called the Legality Movement, headed by Abas Kupi; and (3) a Communist organization called the National Liberation Front (NLF), led by Enver Hoxha. These groups fought against one another as well as against the German occupation forces.

Communist control. In 1944, the Germans were driven out of Albania, and the Communists gained control of the country. Hoxha established a Communist government at Tiranë during that year, and he began ruling the country as first secretary of the Communist Party. The Communists greatly restricted the freedom of the people.

The Communist Party in Yugoslavia had helped the Communists of Albania organize the NLF, and relations with Albania remained close until 1948. But in that year, a split developed between the Soviet Union and Yugoslavia. The split resulted in the expulsion of Yugoslavia from the Cominform, a Soviet-dominated organization of European Communist parties. The people of Albania supported the Soviet Union to free themselves from Yugoslav influence. They also hoped to obtain Soviet aid in gaining control of a part of Yugoslavia where Albanians lived.

Albania's close relations with the Soviet Union ended in the early 1960's. At that time, a break occurred between the Soviet Union and China over the interpretations of certain Communist teachings. In particular, China rejected the Soviet Union's policy of coexistence with non-Communist countries. Albania supported China in the dispute. In 1961, Albania and the Soviet Union broke off relations. At about the same time, Albania limited its contact with most other nations.

China provided Albania with technical assistance and other aid from the 1960's to the late 1970's. Albania then became China's only ally in Europe. Albanian delegates at the United Nations (UN) played a leading role in the efforts that led to China's admission to the UN in 1971.

Relations between Albania and China became strained during the late 1970's. Albania's leaders accused China of abandoning Communist principles. They criticized China for improving relations with Yugoslavia and the United States. In 1978, China responded to these attacks by cutting off all aid to Albania. In the early 1990's, Albania restored relations with the United States, improved relations with China, and increased its contact with other nations. In addition, Albania restored relations with the Soviet Union prior to that country's breakup in 1991.

Hoxha died in 1985, after ruling Albania for more than 40 years. Ramiz Alia succeeded Hoxha as first secretary of the Communist Party. Alia had been elected president of Albania in 1982, and he continued to serve as president. Alia's government introduced some social and economic reforms in an attempt to avoid the downfall suffered by other Communist governments in Eastern Europe in 1989. The government again allowed the public practice of religion. In 1967, the government had outlawed all religious groups and seized their property. In 1990, however, places of worship began to reopen. Another reform called for paying workers bonuses to work harder and produce more goods as a way to ease shortages.

But the people felt that the reforms did not go far enough. In December 1990, Albanians staged protests to try to force the Communists from power. As a result, the Communists allowed the formation of new political parties.

End of Communist rule. In March 1991, multiparty national elections were held. The Communists won a majority of seats in the National Assembly and remained in

power. But protests against Communist rule continued, and the Communist prime minister and his cabinet were forced to resign in June. A temporary government made up of Communists and non-Communists, who had given up their party affiliations, was formed. Thousands of Albanians fled the country to gain more freedom and escape severe economic hardships.

Parliamentary elections in March 1992 gave the Democratic Party a majority of seats. In April, Alia resigned as president. The Assembly then elected Sali Berisha of the Democratic Party as president. Berisha supported the creation of a free-enterprise economy, and his government introduced a program for economic reform.

In parliamentary elections held in 1996, the Democratic Party again won a majority of seats in the National Assembly. However, international observers criticized the elections for ballot fraud and other irregularities.

In January 1997, tens of thousands of Albanians staged violent protests across the country against Berisha's government. The protests began after the collapse of investment schemes in which hundreds of thousands of people lost their savings. Most investors blamed the government for not warning them against the risky investments, and they claimed that the government profited from the funds. Many people demanded Berisha's resignation. He remained in office but formed a coalition government and announced that elections would be held in June. But unrest continued to spread, and Albania fell into disorder. Thousands left the country.

In April, the UN sent an international force to oversee relief efforts and help restore order. In parliamentary elections held in June and July, the Socialist Party defeated Berisha's Democratic Party by a landslide. Socialist

leader Rexhep Meidani became president. Some measure of calm returned, and the UN force left in August.

Recent developments. In 1998 and 1999, almost half a million ethnic Albanian refugees streamed into Albania from the Yugoslav province of Kosovo. They were fleeing attacks by Serbian forces. With help from international organizations, Albania housed the refugees for several months until it was safe for them to return.

In 1998, Albania adopted a new constitution. Meidani signed the constitution into law in November of that year. The Socialist Party retained control of parliament in elections in 2001. Sharon L. Wolchik

Albany (pop. 95,658) is the capital of New York and one of the oldest cities in the United States. It was first settled in 1624 and became a city in 1686. Albany lies on the Hudson River in eastern New York and has an active port, though it is 150 miles (241 kilometers) from the Atlantic Ocean. The Hudson River has been cleaned out and deepened so that ocean ships can reach the city. For the location of Albany, see New York (political map).

Description. Albany, the seat of Albany County, covers 22 square miles (57 square kilometers) on the west bank of the Hudson River. The business district lies on a slope leading down to the river. The historic and inner-city neighborhoods cluster around the downtown area. In the 1900's, the city expanded westward, and newer, more prosperous neighborhoods lie mainly to the west and southwest. Albany and two other cities—Schenectady and Troy—form a metropolitan area of 875,583 people. The area is often called the Capital Region.

The State University of New York (SUNY) has its system headquarters downtown at SUNY Plaza. The University at Albany, SUNY, has two campuses in the city. Other colleges include Albany College of Pharmacy, Albany Law School, Albany Medical College, the College of St. Rose, and Russell Sage College.

Points of interest in the city include the Albany Institute of History and Art; the Ten Broeck, Schuyler, and Cherry Hill mansions, all built in the 1700's; the State Capitol; and the Empire State Plaza, a large complex of government office towers and other buildings. The plaza includes the New York State Museum; the New York State Library; the Egg, an oval-shaped building with two theaters; and the 44-story Corning Tower, the tallest building in the state outside of New York City.

Economy. Albany is a center of government, education, health care, banking, insurance, and other service industries. The city is also an important transportation center. Many of Albany's workers commute, mainly by automobile, from other cities and towns in the Capital Region. The region is sometimes called Tech Valley because of the research universities and high-technology companies located there. Albany International Airport, northwest of the city, serves the region.

Government and history. Albany has a mayor-council form of government. The voters elect the mayor and 16 council members to four-year terms.

Iroquois Indians lived in what is now the Albany area before European settlers arrived. In 1609, the English explorer Henry Hudson and his crew became the first Europeans to reach the site, during a voyage for the Dutch

East India Company, a trading firm. In 1624, Dutch settlers established Fort Orange on the west bank of the Hudson River in what is now downtown Albany. The settlement around the fort became the Village of Beverwyck in 1652. In 1664, the English claimed the region, and the settlement was renamed Albany for the Duke of York and Albany, the English king's brother. On July 27, 1686, Albany received a charter incorporating it as a city.

Albany played a significant role in the American Colonies as an important river port, a fur-trading center, and a military post. The city has the nickname *Cradle of the Union* because American statesman Benjamin Franklin presented his Plan of Union there at the Albany Congress in 1754. His plan was the first formal proposal to unite the American Colonies. In 1797, Albany was chosen as the state capital.

Albany's most rapid period of growth followed the completion of the Erie Canal in 1825. The canal opened the way for barge traffic between Albany and Buffalo and connected the Hudson River to the Great Lakes. Albany's population increased from 12,630 in 1820 to 24,209 in 1830. New York's first railroad, the Mohawk and Hudson, began to operate between Albany and Schenectady in 1831. The city was a major railroad center during the last half of the 1800's. Transportation, commerce, and industry flourished during the late 1800's and early 1900's. Albany had 94,151 people in 1900, and 134,995 by 1950.

During the last half of the 1900's, Albany, like many U.S. cities, lost population to the suburbs, and many retail stores moved to suburban shopping malls. Manufacturing declined, and service industries became increasingly important to the economy. The Empire State Plaza was completed during this period, as part of a downtown renewal program. Ray Bromley

See also Albany Congress; New York.

Albany Congress was a meeting that adopted the first formal proposal for a political union of the American Colonies. It was held in Albany, New York, in June 1754. Representatives from Massachusetts, New Hampshire, Connecticut, Rhode Island, New York, Pennsylvania, and Maryland met with representatives of the Iroquois tribes at the request of the British government. The purpose of the meeting was to win the loyalty of the Iroquois in view of a threatening war with France, and to work out some form of agreement with them. Colonial representatives included James DeLancey (New York), Thomas Hutchinson (Massachusetts), Stephen Hopkins (Rhode Island), William Pitkin (Connecticut), John Penn (Pennsylvania), and Benjamin Franklin (Pennsylvania).

The delegates realized the real problem was to unify the colonies, and several plans were proposed. The congress adopted Franklin's proposal, often called the *Albany Plan of Union.* Under this plan, each colony would send from two to seven representatives to a Grand Council. This council would levy taxes, raise troops, and regulate trade with the Indians. Neither Britain nor the colonies seriously considered the plan. Eleven years later, the Stamp Act Congress of 1765 marked the colonies' next major step toward an American union (see **Revolutionary War in America** [The Quartering and Stamp acts]). Jack N. Rakove

Al Basrah, *al BAHS ruh* or *al BUHS ruh* (pop. 678,000), also called Basra, is one of the largest cities in Iraq. It is also a chief Iraqi port. Al Basrah stands along the Shatt al Arab, a waterway that connects the Tigris and Euphrates rivers and links Al Basrah with the Persian Gulf. The city lies about 55 miles (90 kilometers) from the Persian Gulf. For location, see **Iraq** (map).

Al Basrah was founded by Arabs in A.D. 636 as a military outpost. It became an important trading center. The city was ruled by the Ottoman Empire from 1534 to 1918. It declined in importance under Ottoman rule. The United Kingdom gained control of the city in 1918, at the end of World War I. The city served as a military center under British rule until Iraq gained independence in 1932. Al Basrah became the main port for exporting Iraqi oil and other products. A war took place between Iraq and Iran from 1980 until 1988, when the two countries agreed to a cease-fire. During that time, much of Al Basrah was destroyed. The city was quickly built up after the war. But in 1991, the city was again heavily damaged by bombing in the Persian Gulf War. Later in the year, Al Basrah suffered more damage during fighting between Shiite rebels and the government of Iraq. Michel Le Gall

Albatross, *AL buh traws,* is the name for any one of several kinds of large sea birds. Albatrosses are found over nearly all oceans, except the North Atlantic. The best-known albatross is the *wandering albatross* of southern seas. It has a white body and darker wings and tail. The spread wings may be up to $11\frac{1}{2}$ feet (3.5 meters) from tip to tip. Its bill is long, heavy, and powerful.

The albatross sometimes follows a ship for days, but is seldom seen resting. It feeds on scraps of food thrown from the ship, or on fish and squid. On such food-gathering flights, the wandering albatross has been known to cover more than 9,300 miles (15,000 kilometers) and to maintain an average speed of 35 miles (56 kilometers) per hour for 500 miles (800 kilometers).

Albatrosses come to land only to breed. Thousands of these birds gather on remote islands. The female albatross's single egg is white with brown spots. It is laid on bare ground or in a shallow nest and hatches after about 81 days. The young bird has dark, fluffy down. Two spe-

cies of albatrosses are commonly found along the Pacific Coast of North America. George L. Hunt, Jr.

Scientific classification. Albatrosses are in the albatross family, Diomedeidae. The scientific name for the wandering albatross is *Diomedea exulans.*

See also Animal (picture: The courtship ritual).

Albee, Edward (1928-), is a major American playwright who uses a wide variety of styles ranging from realism to fantasy. He writes about the need for human contact and the illusions his characters embrace to face the meaninglessness of existence. Albee gained international fame with *Who's Afraid of Virginia Woolf?* (1962), a moving examination of power struggles and the combination of cruelty and love in marriage.

Albee won the 1967 Pulitzer Prize for *A Delicate Balance* (1966), a study of family relationships and friendships set in an emotionally sterile suburban atmosphere. He won the 1975 Pulitzer Prize for *Seascape* (1975), a fantasy about a middle-aged couple's ability to move beyond a fear of change and the unknown. He received a third Pulitzer Prize in 1994 for *Three Tall Women* (world premiere in Vienna in 1991), about an aged woman's encounter with mortality.

Albee's first plays were short, probing dramas about the materialism, complacency, and alienation he saw in American society. They were influenced by the *Theater of the Absurd,* a 1950's European drama movement. These plays include *The Zoo Story* (1959), *The Death of Bessie Smith* (1960), *The Sandbox* (1960), and *The American Dream* (1961). Among his other plays were *Tiny Alice* (1964), a symbolic religious drama, and *The Play About the Baby* (1998), in which an older couple strips away the illusions of a younger couple. *The Goat, or Who Is Sylvia?* (2002) is a dark comedy about a man who falls in love with a goat. Edward Franklin Albee was born on March 12, 1928, in Washington, D.C. Thomas P. Adler

Albéniz, *ahl BAY nees* or *ahl VAY neeth,* **Isaac** (1860-1909), a Spanish composer and pianist, was one of the creators of a national style for Spanish music. His most famous composition, *Iberia* (1908), consists of four books of solo piano music. His orchestral works include *Spanish Rhapsody* (1887) and *Catalonia* (1899). From 1893 to 1900, he lived in Paris, where his music influenced the French composers Claude Debussy and Maurice Ravel.

Isaac Manuel Frescesco Albéniz was born on May 29, 1860, in Camprodón in Catalonia. He gave his first piano recital at the age of 4. He was a respected concert pianist throughout his life. Vincent McDermott

Albers, Josef (1888-1976), was a German-born painter and teacher. Albers focused on the way colors are made to perform by their relationship within a picture. He limited himself for years to one form: the square. By painting squares within squares, he explored color relationships with more freedom since he was relieved of the problem of form. He called his series of square paintings *Homage to the Square.*

Albers was born on March 19, 1888, in Bottrop. He taught color theory and abstract art at the Bauhaus school of design from 1923 to 1933, then moved to the United States. Albers taught at Black Mountain College from 1933 to 1939 and at Yale from 1950 to 1960. Albers became partly responsible for the Bauhaus influence on American design. He became a U.S. citizen in 1939. See also Corcoran Gallery of Art (picture). Dore Ashton

Albert I (1875-1934), king of the Belgians from 1909 to 1934, was a heroic military leader during World War I (1914-1918). As commander in chief of the Belgian army, he helped stop the German advance in September 1914. Albert remained in active command of the army until the end of the war. After the war, he helped his country with the problems of reconstruction. In a few years, Belgium had largely recovered from the effects of the war.

Albert was born on April 8, 1875, in Brussels. He was the grandson of King Leopold I, the German prince elected king of the Belgians in 1831. Albert succeeded his uncle, Leopold II, in 1909. He married Elizabeth, Duchess of Bavaria, in 1900. As king, Albert was known for his liberal views and democratic sympathies. A noted sportsman, he died while mountain climbing near Namur, Belgium. His eldest son succeeded him as Leopold III. Jane K. Miller

Albert, Carl Bert (1908-2000), an Oklahoma Democrat, was speaker of the United States House of Representatives from 1971 until he retired in 1977. He had been majority leader of the House since 1962. Albert played an important role in the passage of President Lyndon B. Johnson's domestic program in the mid-1960's. He backed Johnson's civil rights proposals even though his district generally opposed such legislation.

Albert was born on May 10, 1908, in McAlester, Oklahoma. He graduated from the University of Oklahoma and studied at Oxford University in England on a Rhodes scholarship. He began his first House term in 1947 and was majority whip from 1955 to 1962. Albert was chairman of the platform committee of the 1964 Democratic National Convention and was permanent chairman of the party's 1968 national convention. Charles Bartlett

Albert, Lake. See Lake Albert.

Albert, Prince (1819-1861), married his first cousin, Queen Victoria of the United Kingdom, in 1840. As prince consort, he was respected for his industry and business sense. Some distrusted him as the queen's adviser, because he was not born in England. See Victoria.

Albert was born on Aug. 26, 1819, near Coburg, Germany. His father, Ernest, was the Duke of Saxe-Coburg and Saalfeld (from 1826, of Saxe-Coburg and Gotha). Albert's full given name was Francis Charles Augustus Albert Emmanuel. He was educated as a possible *consort* (husband) to Victoria. Victoria ascended to the throne in 1837 and was crowned in 1838. In 1839, Albert visited her. They were married in 1840.

Albert became the adviser and private secretary to the queen. He reorganized the royal household and started a study of politics. In 1841, he was appointed head of a commission to encourage the fine arts in the United Kingdom. He spent his leisure time in museums and art studios, and in parts of London where conditions were either being improved or in need of it. His speeches to the working people showed his ability and tact.

In 1847, Cambridge University elected Albert chancellor. His ideas on education helped alter the academic program, which was soon imitated by Oxford University. At the request of the Duke of Wellington, he helped reorganize the army training plan during the Crimean War. He was interested in agricultural improvements, and he planned and landscaped Victoria's winter home on the Isle of Wight. Late in 1861, Albert's health failed. He died of typhoid fever. Richard W. Davis

The majestic Canadian Rocky Mountains rise along Alberta's southwestern border.

Alberta

Alberta, the westernmost Prairie Province of Canada, is one of the greatest oil-producing regions in North America. About 70 percent of Canada's petroleum comes from oil wells on Alberta's rolling plains. About 80 percent of Canada's natural gas comes from huge deposits that lie near the oil fields. Pipelines carry Alberta's oil and natural gas throughout Canada and into the United States. Alberta's major oil fields lie in the central and northern parts of the province.

Petroleum has helped make Alberta prosperous. Oil and natural gas production fees and leases make up the provincial government's greatest source of income. They have paid much of the cost of Alberta's hospitals, roads, schools, and other public works. Petroleum and natural gas production and related industries provide a large share of the personal income of Alberta's people. Service industries, however, provide the greatest sources of income to the province's people. The province's standard of living is among the highest in Canada.

The contributors of this article are G. Peter Kershaw, Professor of Geography at the University of Alberta; and Roderick C. Macleod, Professor of History at the University of Alberta.

Alberta also has other resources, including more than half of the known coal deposits of Canada. Other minerals found in the province include natural gas liquids, sand and gravel, and sulfur. Alberta's mining production accounts for about three-fifths of the national total.

Alberta is a leading province in agriculture. In many areas of the province, vast fields of golden wheat can be seen extending to the horizon. Among the provinces, Alberta ranks behind only Saskatchewan in its production of wheat, barley, and canola. Alberta also produces more beef cattle than all the other provinces combined.

The production of chemicals is the leading manufacturing activity in Alberta. *Petrochemicals* (chemicals made from petroleum) and fertilizer are the province's chief chemicals. Edmonton is Alberta's capital and second largest city. Calgary is the largest city.

Millions of tourists visit the province yearly. The most popular attractions are the majestic, snow-capped Canadian Rockies along the province's southwestern border. There lie three of Alberta's five national parks—Banff, Jasper, and Waterton Lakes. Lake Louise, which is surrounded by the Canadian Rockies in Banff National Park, is one of the most popular attractions in Canada. Many vacationers go to the province's northern forests to hunt

Interesting facts about Alberta

WORLD BOOK illustrations by Kevin Chadwick

The world's largest Easter egg is located in Vegreville. It is 26 feet (7.9 meters) long, 18 feet (5.5 meters) wide, stands 31 feet (9.4 meters) high on its base, and weighs about 5,000 pounds (2,300 kilograms). It is known as the *Pysanka*, the Ukrainian term for Easter egg. The computer-designed egg has a shell composed of multicolored aluminum pieces joined together to form a colorful pattern.

World's largest Easter egg

The world's largest shopping center is the West Edmonton Mall. It has more than 800 shops, the world's largest indoor amusement park, 20 movie theaters, and an ice arena.

The world's foremost dinosaur museum is the Royal Tyrrell Museum of Palaeontology in Drumheller. Opened in 1985, it has dinosaur fossils from throughout the provinces. The museum is named after Joseph Burr Tyrrell, a Canadian geologist who discovered rich beds of dinosaur fossils in Alberta in 1844.

Head-Smashed-In Buffalo Jump, near Fort Macleod, is a cliff that Indians used to kill large numbers of buffalo. Archaeological evidence shows that the cliff was used for this purpose during different periods between about 3,600 B.C. and the mid-1800's. Indians stampeded buffaloes over the 33-foot (10-meter) cliff while hunters waited below to butcher the animals for meat, hide, and bone. Blackfoot Indians gave the site its present name after a young brave's skull was crushed while he watched from below as buffaloes were being driven over the cliff. They called the place Estipah-Sikikini-kots, meaning "where he got his head smashed in."

Head-Smashed-In Buffalo Jump

Pedestrian mall in downtown Calgary

bears, caribou, deer, elk, and moose, or to fish in the sparkling lakes and streams. Others stay at dude ranches in Alberta's cattle country. Hikers visit the forts, missions, and trading posts that were built during Alberta's fur-trading days. Winter skiing in the Canadian Rockies is also an attraction. Unusually clear skies give Alberta more hours of sunshine throughout the year than any other Canadian province, and earned it the nickname *Sunny Alberta.*

The name of the province dates from 1882. During that time, the Canadian government decided to divide the region of land lying between Manitoba and British Columbia into four territorial districts—Alberta, Assiniboia, Athabaska, and Saskatchewan. The Alberta district was named after Princess Louise Caroline Alberta, a daughter of Queen Victoria. The princess was married to the Marquess of Lorne, the Canadian governor general. The princess' first name was given to what is now Alberta's most famous lake, Lake Louise in Banff National Park.

For Alberta's relationship to the other provinces of Canada, see the *World Book* articles on Canada; Canada, Government of; Canada, History of.

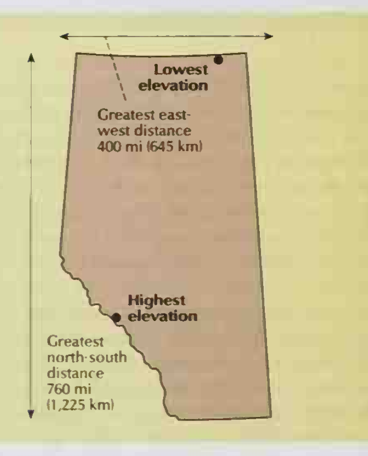
Alberta in brief

Symbols of Alberta

The provincial flag, adopted in 1968, bears the shield from the coat of arms. The shield has a cross of St. George, which represents Alberta's link with the United Kingdom, and a landscape with mountains, hills, a prairie, and a field of wheat. The shield was adopted as the provincial coat of arms in 1907. A lion and a pronghorn supporting the shield and a crest including a helmet, a beaver, and a crown were added in 1980.

Provincial flag

Alberta (brown) is the fourth largest province and the largest of the Prairie Provinces (yellow).



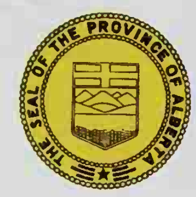
The Legislature Building is in Edmonton, the capital of Alberta since it entered the Dominion in 1905.

General information

Entered the Dominion: Sept. 1, 1905, with Saskatchewan, as the 8th and 9th provinces.
Provincial abbreviation: AB (postal).
Provincial motto: *Fortis et Liber* (Strong and Free).

Land and climate

Area: 255,287 mi² (661,190 km²), including 6,490 mi² (16,800 km²) of inland water.
Elevation: *Highest*—Mount Columbia, 12,294 ft (3,747 m) above sea level. *Lowest*—557 ft (170 m) above sea level along the Slave River in northern Alberta.
Record high temperature: 110 °F (43 °C) at Bassano Dam on July 21, 1931, and at Fort Macleod on July 18, 1941.
Record low temperature: −78 °F (−61 °C) at Fort Vermilion on Jan. 11, 1911.
Average July temperature: 63 °F (17 °C).
Average January temperature: 9 °F (−13 °C).
Average yearly precipitation: 16 in (41 cm).



Important dates

- **1754-1755** Anthony Henday of England explored the Alberta region.
- **1778** Peter Pond of the United States established a trading post near Lake Athabasca.
- **1874** The North-West Mounted Police established Fort Macleod.
- **1876-1877** Indians surrender central and southern Alberta to the government through two treaties.
- **1883** The Canadian Pacific Railway reached Calgary.

Members of the House of Commons: 26
Members of the Senate: 6

Sources of information

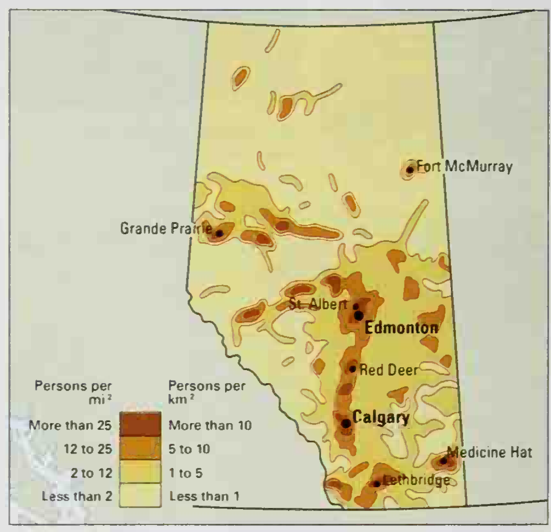
For information on tourism and vacation planning in Alberta, write to: Travel Alberta, Box 2500, Edmonton, AB T5J 2Z4. Travel Alberta's Web site at www.travelalberta.com also provides tourist information. The Provincial Archives of Alberta handles requests for information about the province's economy, government, and history. Write to: Provincial Archives of Alberta, 12845 102nd Avenue, Edmonton, AB T5N 0M6. The Alberta government's Web site at www.gov.ab.ca also serves as a useful gateway to information on the province's economy, government, and history.

1905 — Alberta became a province on September 1.

1914 — The province's first major oil discovery was made in Turner Valley.

1967 — Alberta's first plant to remove oil from bituminous sands began operation.

Population. The 2001 Canadian census reported that Alberta had 2,974,807 people. The population had increased about 10 percent over the 1996 census figure of 2,696,826 people.



About 80 percent of Alberta's people live in cities, towns, and villages. About two-thirds of them live in the metropolitan areas of Calgary and Edmonton. These two cities have Alberta's only Census Metropolitan Areas as defined by Statistics Canada. For the populations of the province's cities, towns, and other populated places, see the *Index* to the political map of Alberta.

Most of Alberta's people live in the southern part of the province. Cold Lake and Grande Prairie are the only cities in the northern half of the province with populations of over 10,000. Calgary is Alberta's largest city, followed by the province's capital, Edmonton. For further information, see the separate articles on the cities and towns of Alberta listed in the *Related articles* at the end of this article.

About 84 of every 100 Albertans were born in Canada. About a third of the rest of Alberta's people came to the province from the United Kingdom or the United States. About 45 percent of the people have English ancestors. Other large ethnic groups in the province, in order of size, are those of Scottish, German, Irish, French, Ukrainian, Dutch, or Polish descent.

Population density

Most of Alberta's people live in the southern part of the province—especially in and around Calgary and Edmonton, the province's largest cities. The northern areas are thinly settled.

Alberta has approximately 70,000 people of Indian ancestry, about 25,000 of whom live on reservations. The tribes include the Blood, Cree, Piegan, and Siksika (North Blackfoot). About 40,000 *métis* (people of mixed Indian and white descent) also live in the province. About 7,000 Hutterites live in Alberta, more than in any other province. The members of this religious group are successful farmers who lead simple lives. They live in about 80 communities, most in southwestern Alberta or northeast of Calgary. Many families include nine or more children. The Hutterites came to Alberta from South Dakota in 1918. They had been persecuted in South Dakota during World War I (1914-1918) for refusing to bear arms for religious reasons. See **Hutterites**.

Schools. Missionaries established the first schools in the Alberta area during the mid-1800's. A public school system was set up in the province in 1884. Today, Alberta has public, separate, and private schools. Elected boards of trustees administer the public and separate school systems. Private schools are organized by private groups and offer a variety of academic, religious, or language instruction. Public and separate schools are supported by taxes. Public education also offers fully funded *charter schools*. These schools operate under local control according to the terms of special contracts called *charters*. Private schools receive funding from private sources. Accredited private schools may qualify for partial provincial funding. Parents may also choose home education programs supervised by a school board or an accredited private school.

All Alberta schools are governed by the provincial Department of Learning, which is headed by the minister of learning. Alberta law requires all children from the ages of 6 to16 to attend school. For the number of students and teachers, see **Education** (table).

Universities and colleges

This table lists the universities and colleges in Alberta that grant bachelor's or advanced degrees and are members of the Association of Universities and Colleges of Canada.

Name	Mailing address
Alberta, University of	Edmonton
Athabasca University	Athabasca
Augustana University College	Camrose
Calgary, University of	Calgary
Concordia University College of Alberta	Edmonton
King's University College	Edmonton
Lethbridge, University of	Lethbridge

Libraries and museums. Alberta has many public libraries throughout the province. The University of Alberta in Edmonton, the University of Calgary, and the University of Lethbridge have large academic libraries.

The Glenbow Museum in Calgary features exhibits on the history of Alberta and western Canada. The Provincial Museum of Alberta in Edmonton also has exhibits on Alberta's history. The Royal Tyrrell Museum of Palaeontology, in Drumheller, has a large collection of dinosaur fossils. The Odyssium, in Edmonton, has exhibits on science, as well as a planetarium, an observatory, and an IMAX theater. Fort Edmonton Park, in Edmonton, features re-creations of Edmonton streets from different periods in the city's history. Heritage Park in Calgary and Ukrainian Cultural Heritage Village near Edmonton are also pioneer villages. The Remington-Alberta Carriage Centre in Cardston has horse-drawn vehicles from the 1800's and early 1900's. The Reynolds-Alberta Museum in Wetaskiwin exhibits old-time automobiles, farm equipment, and aircraft. Calgary, Edmonton, Lethbridge, Medicine Hat, and Red Deer have art galleries.

Visitor's guide

Every year, millions of visitors come to Alberta from all over the world. Vacationers are especially attracted by the province's world-famous national parks in the majestic Canadian Rockies. Tourists may ride horseback and may enjoy boating, golfing, swimming, and white water rafting amid spectacular scenery. Mountain climbers face the challenge of Alberta's jagged slopes. In winter, skiers skim down mountain slopes in areas such as Banff, Jasper, and Kananaskis.

Trails for hikers lie throughout the province. Each year, many vacationers travel to northern Alberta to fish in the province's sparkling lakes and streams for grayling, trout, pike, and walleye. Many other tourists stay at guest ranches and farms. The Calgary Stampede is one of Alberta's most popular annual events. This 10-day rodeo is held in Calgary each July.

Places to visit

Following are brief descriptions of some of Alberta's many interesting places to visit. See also entries about other attractions in the *Interesting facts about Alberta* section in the introduction of this article.

Badlands, in the Red Deer River Valley, have weird and beautiful rock shapes—called *hoodoos*—created by wind and water erosion. The rock layers contain fossils of dinosaurs and other forms of life.

Calgary Zoo features natural habitat enclosures, a tropical aviary and conservatory, and life-sized dinosaur models.

Columbia Icefield, between Banff and Jasper, consists of about 150 square miles (390 square kilometers) of glacial ice. Tourists ride in a snowcoach over Athabasca Glacier.

Dinosaur Provincial Park, northeast of Brooks, was established in 1955 to protect one of the most extensive dinosaur fields in the world. Visitors can tour the park.

Fort Museum, in Fort Macleod, has a full-size replica of the Alberta region's first North-West Mounted Police outpost, built in 1874. The museum explores the history of American Indians, pioneers, and police in the region.

Frank Slide Interpretive Centre, located near the southwestern bor-der of Alberta, is the site of a 1903 landslide. Visitors can explore the slide area and learn about the early coal miners.

National parks. Alberta has about 21,000 square miles (54,000 square kilometers) of national parks, more than in any other province. The first Canadian national park was established in Alberta in 1885. This park is now known as Banff National Park. Alberta has four other national parks—Elk Island, Jasper, Waterton Lakes, and Wood Buffalo. See **Canada** (National park system).

Provincial parks. Alberta has 65 provincial parks and over 200 provincial recreation areas. For information, write to: Alberta Environment, 9915 108th Street, Edmonton, AB T5K 2G8. Alberta Environment's Web site at www.gov.ab.ca/env/parks also provides information on Alberta's provincial parks.

Land and climate

Land regions. Alberta has four main land regions. They are (1) the Canadian Shield, (2) the Saskatchewan Plain, (3) the Alberta Plain, and (4) the Rocky Mountains and Foothills. These regions increase in altitude toward the Canadian Rockies in the southwest.

The Canadian Shield is a vast, horseshoe-shaped region that covers almost half of Canada and extends into the United States. This hilly section, made up of ancient granites and other rocks, covers a small part of the northeastern corner of Alberta. Most of the region lies less than 1,000 feet (300 meters) above sea level. The lowest point in Alberta, 557 feet (170 meters) above sea level, is along the Slave River. The region has forests of *coniferous* (cone-bearing) trees and many lakes. It is thinly populated. See **Canadian Shield**.

The Saskatchewan Plain is part of the Western Interior Plains, the Canadian section of the North American Great Plains. Pine and spruce forests cover much of this gently rolling region. Alberta's *bituminous sands* (sands that contain a substance from which oil can be obtained) are found along the lower Athabasca River. The Saskatchewan Plain lies less than 2,000 feet (610 meters) above sea level.

The Alberta Plain, another part of the Western Interior Plains, is the province's largest land region. It covers about two-thirds of Alberta. Most of this region has an altitude of more than 2,000 feet (610 meters). Pine and spruce forests cover the northern part of the Alberta Plain. Grasslands with some aspen groves lie near Grande Prairie and north of the Peace River between the North Saskatchewan River and Grimshaw. The area between the North Saskatchewan River and the Red Deer River is called the Parklands. This area has groves of aspen trees within grasslands. It is Alberta's chief farming region and one of the richest in Canada. It has rich soils and regular rainfall. Parklands farms produce crops and livestock. To the south, the Alberta Plain ranges from gently rolling to flat grassland. There, wheat and other grains grow well, and ranchers raise cattle and sheep.

The Rocky Mountains and Foothills extend through western North America between Northern Alaska and New Mexico in the United States. They are part of the great Cordilleran mountain chain that reaches to the southern tip of South America. In Alberta, the Canadian Rockies rise along the Great Divide, which forms the province's southwestern border with British Columbia (see **Great Divide**). Mount Columbia, the highest point in Alberta, rises 12,294 feet (3,747 meters). The Twins (north peak 12,085 feet or 3,684 meters, and south peak 11,675 feet, or 3,559 meters) tower over Jasper National Park. Thirty other mountains in the region are higher than 10,000 feet (3,000 meters).

The Canadian Rockies have some of the most spectacular scenery in the world. The snow-capped peaks consist of bare, jagged rock. Thick growths of aspens, balsam firs, pines, poplars, and spruces cover the northern foothills. They provide much lumber and pulpwood for Alberta's forest industries. The rugged Rockies attract many mountain climbers. The Rockies also appeal to people who enjoy sport fishing in the high lakes and streams or hunting mountain goats and sheep in designated areas. Banff, Jasper, and Waterton Lakes national parks are in this beautiful region.

Rivers and lakes. Northern and north-central Alberta are drained by the Athabasca, Hay, and Peace rivers and their tributaries. In warm weather, barges and tugboats operate on the Athabasca River. They can travel as far as the Arctic. The North Saskatchewan River and its branches, including the Battle and Vermilion rivers, drain the Parklands in south-central Alberta. The North Saskatchewan River rises in the Columbia Icefield, which lies in Banff and Jasper national parks and in British Columbia. This 100-square-mile (260-square-kilometer) sheet of ice consists of glaciers made of ice that may be hundreds of years old. Most of Alberta's major rivers originate in the mountains. Their water comes mostly from melting snow and glaciers.

Alberta Agriculture

Vast wheat fields cover much of the southern Alberta Plain. Fertile soil and regular rainfall help make the Alberta Plain the major farming region of the province. Wheat is Alberta's chief crop. The province is also an important producer of barley, oats, and rye.

Lake Athabasca is the largest lake in Alberta. A third of this 3,064-square-mile (7,935-square-kilometer) lake lies in northeastern Alberta, and the rest is in Saskatchewan. Other large lakes in Alberta include Lake Claire in the northeast and Lesser Slave Lake in the central region. Beautiful Lake Louise in Banff National Park is Alberta's most famous lake.

Plant and animal life. Forests cover about half the province. Important trees include balsam poplar, balsam fir, Douglas-fir, jack pine, lodgepole pine, tamarack, trembling aspen, and black, white, and Engelmann spruce. Flowers in Alberta bloom from early spring, when crocuses appear, to autumn, when frost withers the goldenrods and asters. The provincial flower, the wild rose, grows throughout the province. Purple fireweeds, which thrive on scorched forest lands, quickly cover the woodlands after a fire. Blueberries, chokeberries, highbush cranberries, raspberries, saskatoons, and strawberries grow over much of the countryside.

Alberta lies along three of the major North American flyways used by birds migrating between their winter and summer homes (see **Bird** [How birds migrate]). Many kinds of songbirds live in the river valleys. Game birds, especially ducks and geese, nest on lakes and sloughs throughout the province. Many wetlands are managed to improve nesting success.

Alberta has many native mammals. Several species of ground squirrels live in the province. Snowshoe hares are found throughout Alberta. Pronghorns and mule and white-tailed deer are common in the grasslands. Black bears, caribou, chipmunks, elk, moose, mule deer, tree squirrels, and white-tailed deer can be found in the forests. Bighorn sheep, elk, grizzly bears, mountain goats, mountain lions, and mule deer inhabit the mountains of Alberta.

Bears, beavers, coyotes, ermines, fishers, foxes, lynxes, martens, minks, muskrats, squirrels, wolves, and wolverines are common in the northern half of the province. Some native people in this area make a living by trapping these animals for fur.

Important species of fish in the lakes and rivers of Alberta include grayling, pickerel, pike, trout, and whitefish. Several species of reptiles are found in the southern parts of the province. But these animals are less common in the cooler northern areas.

Climate. Alberta has long, cold winters and short, warm summers. Temperatures in both summer and winter are generally much lower in the north than in the south. January temperatures in the province average 5 °F (−15 °C), and July temperatures average 59 °F (15 °C). Fort Vermilion had the lowest recorded temperature, −78 °F (−61 °C), on Jan. 11, 1911. Medicine Hat had the highest, 108 °F (42 °C), on July 12, 1886. *Precipitation* (rain, melted snow, and other forms of moisture) averages 12 to 21 inches (30 to 53 centimeters) yearly. Annual snowfall ranges from about 70 inches (180 centimeters) in the north to 30 inches (76 centimeters) in the south.

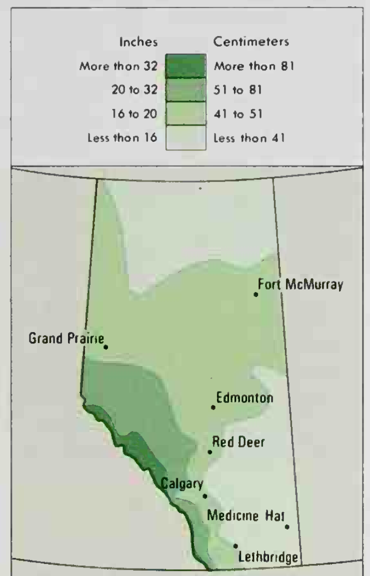
Average January temperatures

Alberta has long, cold winters. The province's temperatures decrease steadily from the south to the far northern region.

Degrees Fahrenheit / Degrees Celsius
Above 10 / Above -12
0 to 10 / -18 to -12
-8 to 0 / -22 to -18
Below -8 / Below -22
Fort McMurray
Grande Prairie
Edmonton
Red Deer
Calgary
Medicine Hat
Lethbridge



Average July temperatures

The province has short, mild summers. The southeastern part of Alberta has the warmest summertime temperatures.

Average yearly precipitation

Precipitation varies widely throughout the province. The north and southeast are much drier than the southwestern area.

WORLD BOOK maps; based on the *National Atlas of Canada.*

Economy

In the early days, the economy of the Alberta region was based chiefly on the fur trade. Agriculture became important during the late 1800's. Petroleum and natural gas became important sources of income during the 1950's. Today, Alberta has a diversified economy built on agriculture and resource-based industries. Service industries, taken together, account for the largest portion of Alberta's *gross domestic product* (GDP)—the total value of all goods and services produced in the province in a year. Mining is Alberta's second most important economic activity. It accounts for about a fifth of the province's gross domestic product.

Natural resources. Alberta's fertile soil helps produce plentiful crops. Its vast mineral deposits supply important industries. The provincial government owns most of the mineral and forest resources, and enforces strict regulations to protect them and the land.

Soil. The brown soil of the southeastern prairies, which gets little rain, is the only soil in Alberta that requires irrigation. The rich, dark-brown or black soil of the other prairies receives more rain and produces much of Alberta's grain. The Parklands have the richest topsoil, much of it 1 foot (30 centimeters) thick. The uplands and northern forests have gray soil.

Minerals. Alberta has about 5 billion barrels of oil deposits in underground pools. After an oil well has been drilled, provincial laws require the oil companies to remove the drilling rig and restore the land to its former state. In the Athabasca River Valley, bituminous sands are so soaked with oil that a person gets oily handling them. Indians and fur traders once used these sands to make their canoes watertight. Experts estimate that the oil-sands deposits extend 54,000 square miles (140,000 square kilometers) and contain as much as $1\frac{1}{2}$ trillion barrels of oil. These are among the world's largest known reserves. About 95 trillion cubic feet (2.7 trillion cubic meters) of natural gas lie underground, most of it near oil fields.

Most of Canada's known coal reserves lie in Alberta. Coal beds cover 117,000 square miles (303,000 square kilometers) from the foothills of the Rockies through much of the central and southern plains. Most of Alberta's deposits consist of soft forms of coal called *bituminous coal* and *subbituminous coal.*

Sand and gravel are found throughout the province. Fine limestone occurs on the eastern slopes of the Rocky Mountains, and clay and shale are plentiful in the Medicine Hat area. Thick salt beds are found in the northeast and near Edmonton. Other mined products include potash, quartz, sodium sulfate, and sulfur.

Service industries, taken together, account for the largest portion of Alberta's gross domestic product. The province's service industries are concentrated in the Calgary and Edmonton metropolitan areas.

Community, business, and personal services is Alberta's most important economic activity in terms of gross domestic product. This industry group is also the leading employer in the province. These services include such activities as education, health care, legal services, engineering services, and the operation of hotels, restaurants, and recreational facilities. This service group benefits heavily from the thousands of tourists that visit the province each year. Banff National Park in the Rocky Mountains and the cities of Calgary and Edmonton rank

Production and workers by economic activities

Economic activities	Percent of GDP* produced	Employed workers: Number of people	Percent of total
Community, business, & personal services	20	601,900	38
Mining†	19	83,300	5
Finance, insurance, & real estate	16	79,000	5
Manufacturing	10	140,100	9

among Alberta's leading tourist destinations.

Finance, insurance, and real estate form the second most important service industry group in terms of gross domestic product. This group benefits greatly from income brought in by the province's petroleum and gas industries. For example, each year the provincial government collects millions of dollars in royalties from petroleum companies, which it invests in the province's financial institutions. The government sets aside money for investments so it will have money to draw on at times that oil and gas revenues decline.

Ranking next among Alberta's service industries are (1) wholesale and retail trade and (2) transportation and communication. Each of these groups accounts for an equal share of the province's gross domestic product.

The province's wholesale trade is based mainly on the distribution of food and mined products. Alberta exports large amounts of petroleum and natural gas to the United States. Retail trade establishments include department stores, grocery stores, and specialty shops. These businesses also benefit from tourist spending.

Telecommunications is a major part of the transportation and communication sector. More information on this industry group appears later in this section.

Government ranks fifth. Many government activities are centered in Edmonton, Alberta's capital.

Mining. Petroleum is Alberta's leading mineral product, and the province produces about 70 percent of Canada's oil. About 55,000 wells in Alberta yield about 600 million barrels of petroleum each year. Alberta's major oil fields are at Judy Creek, Pembina, Rainbow Lake, Redwater, and Swan Hills. The province has two large plants that produce petroleum from oil sands. These plants lie near Fort McMurray in the Athabasca River Valley. Smaller plants operate at Cold Lake and Peace River. Petroleum produced from oil sands accounts for about 40 percent of the province's total oil production.

Alberta produces about 80 percent of Canada's natural gas. Pipelines carry petroleum and natural gas throughout Alberta and to the east, south, and west. Gathering lines transport the fuels within the province and feed them into cross-country lines. The Interprovincial Pipeline starts in Redwater, near Edmonton. It carries Alberta oil about 2,600 miles (4,100 kilometers) east to Quebec City. The Trans Mountain Pipeline carries oil 718 miles (1,156 kilometers) west, from Edmonton to refineries in Vancouver, British Columbia. Alberta pipelines feed natural gas into the Trans-Canada Pipeline, which extends over 2,300 miles (3,700 kilometers) from the Alberta-Saskatchewan border to Quebec City. All these pipelines have branches into the United States. In addition, a network of pipelines 1,370 miles (2,200 kilometers) long carries natural gas from Alberta to California. The Trans-Canada Pipeline, with all its branches, is the longest pipeline in Canada.

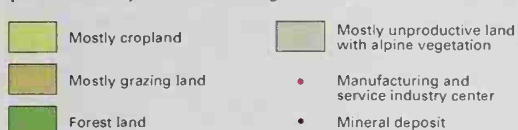
Petroleum and natural gas account for more than 90 percent of Alberta's mining income. Of the province's other mined products, coal, sand and gravel, and sulfur are most important. Vast deposits of coal lie in southern Alberta. Most of the coal is obtainable by surface mining. Major surface mining operations take place to the west of Edmonton and to the east of Red Deer. Much of Alberta's sand and gravel production occurs in the south-central part of the province. Sand and gravel are used mainly for building roadbeds. Almost all of Alberta's sulfur comes from processing natural gas. Sulfur is used in the manufacture of paper and fertilizer.

Manufacturing. Goods produced in Alberta have a *value added by manufacture* of about 14 billion Canadian dollars yearly. This figure represents the difference between the value of raw materials and the value of finished products manufactured from the raw materials.

The production of chemicals is the leading manufacturing activity in Alberta. The province's main chemical products are petrochemicals and fertilizers. Petrochemicals are produced from petroleum and include such compounds as ethylene and methanol.

Food and beverage processing is Alberta's second most important manufacturing activity in terms of annual value added by manufacture. Meat packing is the leading type of food processing in Alberta. The Calgary area is a major center of Canada's meat-packing industry. Other important products include animal feed, beer, dairy products, and flour.

Other leading products manufactured in Alberta include fabricated metal products, paper and allied products, and wood products. Machine tools, metal containers, and structural metal are the main fabricated metal products. Newsprint is the primary type of paper produced in the province. Leading wood products include lumber, cabinets, doors, and window frames.



Agriculture. Alberta has approximately 55,000 farms. Farmland covers about a third of the land area. Alberta has about two-thirds of Canada's irrigated farmland.

Beef cattle are the leading farm product in Alberta, providing nearly half of the annual farm income. The heaviest concentration of cattle ranches lies in a wide belt that begins north of Calgary and extends to the U.S. border. Alberta has more beef cattle than any other province. Farmers in Alberta also raise large numbers of dairy cattle, hogs, and sheep.

Wheat, the leading crop in Alberta, is grown through-

Economy of Alberta

This map shows the economic uses of land in Alberta and where the province's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

out much of the province. Only Saskatchewan produces more wheat. Other leading crops include canola, barley, and ornamental plants. Canola is used to make cooking oil, and barley is used mainly as livestock feed.

Forestry. Alberta has vast timber resources. Forests cover about half of Alberta's land area. Forests grow primarily in the northern and western parts of the province. Softwoods, such as spruce and pine, are the most valuable species. Aspen hardwoods are also important. Most timber is used for lumber and for pulp and paper. The provincial government regulates timber harvesting.

Electric power and utilities. Coal is the chief fuel for power plants in the province. Three major stations have been built near deposits of easily mined coal. Natural gas is also used to fuel power plants. Several hydroelectric stations are on the Bow River and its branches, and on the Brazeau River. Utilities in the province also provide gas and water service.

Transportation. Alberta has a fine highway system. Two transcontinental highways, the Yellowhead and the Trans-Canada, cross Alberta from east to west. The North/South Trade Corridor provides an important connection between northern Alberta and markets in the southern part of the province.

Major airports at Calgary and Edmonton offer both domestic and international service. Alberta also has eight regional airports with scheduled service. Many small airports handle important cargo traffic for northern Alberta, the Northwest Territories, and Yukon Territory. Alberta is the headquarters for WestJet, an airline that serves mainly western Canada.

Alberta has an excellent system of railroads. Two transcontinental rail lines, the Canadian National Railway and the Canadian Pacific Railway, cross the province from east to west. They connect Alberta's exporters of grain, coal, and forest and petroleum products with western ports. The head office of the Canadian Pacific is in Calgary. Alberta is also home to the Central Western Railways, another important railroad system.

Water transportation declined after the province's fur-trading days. However, the discovery of petroleum in Alaska and the Northwest Territories renewed interest in water transportation. In warm weather, barges carry freight on the Athabasca River and the Slave River, which link northern regions of Alberta with the northern part of the Northwest Territories. In winter, airplanes equipped with landing skis and other special equipment are used to haul freight on frozen lakes and rivers.

Communication. The first newspaper in the Alberta region was the *Edmonton Bulletin,* published from 1880 to 1951. Alberta has 9 daily newspapers and about 110 weeklies. *The Edmonton Journal* is the largest daily newspaper. Alberta's first radio station, CFAC in Calgary, began broadcasting in 1922. The province's first television station, CHCT-TV, also in Calgary, started in 1954. Today, Alberta has about 60 radio stations and 11 television stations. Cable television systems and Internet providers serve many Alberta communities.

Government

Lieutenant governor of Alberta represents the British monarch, Queen Elizabeth II, in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada for a period of at least five years. The position of lieutenant governor is largely honorary.

Premier of Alberta is the actual head of the provincial government. Alberta, like Canada itself, has a parliamentary form of government. The premier of the province is an elected member of the Legislative Assembly. The person who serves as Alberta's premier is usually the leader of the party holding the most seats in the Legislative Assembly.

The Executive Council includes ministers who are chosen by the premier from among members of the premier's party in the Legislative Assembly. Each minister directs one or more departments of the provincial government. The Executive Council, like the premier,

Alberta Legislature

Alberta's legislature, called the Legislative Assembly, has one house. Its members serve terms of up to five years.

resigns if it loses the support of a majority of the Legislative Assembly.

Legislative Assembly of Alberta is a one-house legislature that makes the provincial laws. It has 83 members, each of whom is elected from a separate electoral district called a *constituency*. The members' terms may last up to five years. However, the lieutenant governor, on the advice of the premier, may call for an election before the end of the five-year period. If this is done, all members of the Assembly must run again for office.

Courts. The highest court in Alberta is the Court of Appeal. It hears only appeals in civil and criminal cases. The Court of Appeal has the chief justice of Alberta and 12 justices of appeal. The Court of Queen's Bench hears all cases involving murder, treason, and other major crimes. This court has a chief justice, an associate chief justice, and 61 judges.

Judges of Alberta's Court of Appeal and the Court of Queen's Bench are appointed by the governor general in council. They can serve until the age of 75. Provincial court judges hear provincial, civil, family, and youth cases and are appointed by the lieutenant governor in council. The Provincial Court of Alberta consists of a chief judge, 9 assistant chief judges, and 99 judges.

Local government. Alberta has 64 rural municipalities, 15 cities, 110 towns, 105 villages, and 52 summer villages. Each of these incorporated units of local government is self-regulated. A summer village is a community or municipality in a resort area that provides municipal services throughout the year.

The voters of each city and town in Alberta elect a mayor and council to three-year terms. The council consists of seven councilors unless the council passes a bylaw that specifies a higher or lower odd number. Village and summer village voters elect three or five councilors to three-year terms. Every year, the councilors choose one of their number as mayor. Voters in Alberta's counties and municipal districts also elect councilors to three-year terms. Every year, these councilors choose one of their number to serve as *reeve* (chief official). In some cases, the council passes a bylaw that requires the reeve to be elected by the people of the municipality.

Alberta also has eight unincorporated improvement districts, three special areas, and two specialized municipalities. The provincial Department of Municipal Affairs manages these units of local government. Elected councilors serve in advisory roles.

Revenue. Taxation accounts for the largest portion of the provincial government's *general revenue* (income). The next largest source of general revenue comes from the government's charges for rights to petroleum deposits. In the past, some of this money was invested in a special fund. Investments made with the fund's money continue to provide revenue. Like other provinces, Alberta receives financial aid from the federal government. Alberta is the only province with no sales tax.

Politics. Since Alberta became a province in 1905, four parties have controlled its political life. The Liberal Party was the first to control the provincial government. It held power from 1905 until 1921. In 1921, the United Farmers of Alberta came into office. It was formed during a period of low farm prices. During the Great Depression of the 1930's, the people of Alberta became dissatisfied with the government's failure to solve the province's economic problems. A new party, the Social Credit Party, won control of the provincial government in 1935. The Progressive Conservative Party has controlled Alberta's Legislative Assembly since 1971.

The premiers of Alberta

	Party	Term
Alexander C. Rutherford	Liberal	1905-1910
Arthur L. Sifton	Liberal	1910-1917
Charles Stewart	Liberal	1917-1921
Herbert Greenfield	United Farmers of Alberta	1921-1925
John E. Brownlee	United Farmers of Alberta	1925-1934
Richard G. Reid	United Farmers of Alberta	1934-1935
William Aberhart	Social Credit	1935-1943
Ernest C. Manning	Social Credit	1943-1968
Harry E. Strom	Social Credit	1968-1971
Peter Lougheed	Progressive Conservative	1971-1985
Donald R. Getty	Progressive Conservative	1985-1992
Ralph Klein	Progressive Conservative	1992-

History

Indian days. When Europeans first arrived in the Alberta region, the Blackfoot Indian nation lived in the southern prairies and foothills. It consisted of the Blood, Piegan, and Siksika (North Blackfoot) tribes. The Sarcee, their allies, also lived in the south. The Cree lived in the northern forests. Other Indians of the Alberta region included the Beaver and Gros Ventre tribes, and the Stonies, a branch of the Assiniboine tribe.

The fur trade. In 1670, King Charles II of England granted fur-trading rights in the Alberta region to the

Hudson's Bay Company. The region was part of a vast territory called Rupert's Land. The first white person known to visit the Alberta region was Anthony Henday. In 1754, the Hudson's Bay Company sent Henday to promote trade with the Blackfoot Indians. He stayed with the Blackfoot that winter and returned to York Factory, on Hudson Bay, in 1755. See **Henday, Anthony; Hudson's Bay Company.**

In 1778, Peter Pond, an American, built a fur-trading post near Lake Athabasca. During the 1780's, the North West Company, formed by fur traders in Montreal, began to compete with the Hudson's Bay Company. The firms competed in the Alberta region until they combined in 1821. See **North West Company.**

In 1788, Roderick Mackenzie, a fur trader, established Fort Chipewyan. His cousin, Sir Alexander Mackenzie, traveled from this post to the Arctic Ocean in 1789 and to the Pacific Ocean in 1792-1793 (see **Mackenzie, Sir Alexander**). Between 1789 and 1812, the geographer David Thompson made surveys that provided the first good map of the Canadian Northwest.

The missionaries. During the mid-1800's, most of the settlers in the Alberta region were traders and *métis* (people of mixed Indian and white descent). Missionaries converted many Indians. They introduced schools and attempted to persuade Indians and métis to settle permanently and begin farming.

Robert T. Rundle, a Methodist, was the first missionary in the region. He arrived in 1840 and stayed until 1848. Two other Methodist leaders, George McDougall and his son, John McDougall, arrived in the Alberta region in 1863. A priest named Jean Thibault established Alberta's first Roman Catholic mission in 1843 in Lac Ste. Anne. In 1852, Albert Lacombe, another Catholic priest, began working among the Indians and métis. Lacombe founded the town of St. Albert in 1861.

Early settlement. In 1870, the Hudson's Bay Company gave up Rupert's Land to the British government, which then transferred it to the newly formed Dominion of Canada. The dominion paid the company $\$1\frac{1}{2}$ million and permitted it to keep large areas of the plains. Later in 1870, Canada established the North West Territories, which included the Alberta region and the rest of the former Rupert's Land.

At this time, traders from Montana were carrying on an illegal liquor trade with the Indians in the North West Territories. To stop this trade and to prepare the way for peaceful settlement of the region, the Canadian government organized the North-West Mounted Police (see **Royal Canadian Mounted Police** [History]). The Mounties established their first post in the Alberta region in 1874 at Fort Macleod, and stopped the illegal trading. The Mounties won the confidence and respect of the Indians. Within a few years, the Indians and the Canadian government signed three treaties. Treaty No. 6, signed in 1876 and Treaty No. 7, signed in 1877, gave the Canadian government the central and southern parts of Alberta in return for reservations, annual payments, and promises of future assistance for the Indians. Treaty No. 8, signed in 1899, gave the northern half of Alberta to Canada on similar terms.

By 1883, about 500 settlers, most of them cattle ranchers, were living in the Alberta region. That year, the Canadian Pacific Railway (now called CP Rail System) linked Calgary with cities in eastern Canada. The North West Rebellion of 1885, an uprising of Indians and métis led by Louis Riel, caused great alarm in the Alberta region. However, the only violence in the area was the killing of nine whites by Indians at Frog Lake. See **North West Rebellion.**

A new province. Opportunities for settlement in the Alberta region drew thousands of farmers from eastern Canada, the United States, and northern and central Europe. In 1905, the Canadian government established the province of Alberta. Alexander C. Rutherford, a Liberal, became the first premier. Alberta's first major oil discovery was made in 1914, in Turner Valley.

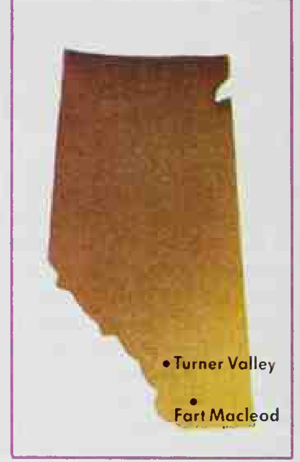
After World War I (1914-1918), many farmers lost their land because of drought and low prices on farm products. The United Farmers of Alberta, a new political party, won control of the provincial government from the Liberal Party in 1921. The new party received support from the farmers, who felt it could best protect their interests. Prosperity returned soon. The provincial government improved and expanded education, highways, and public health programs.

Low farm prices during the Great Depression of the 1930's helped bring another new party to power in Alberta. The Social Credit Party, led by William Aberhart, was elected in 1935. It had promised to solve the problems of the depression. The new government did pass laws to control banking and credit, but the federal government declared these laws unconstitutional.

The mid-1900's. Alberta prospered during World War II (1939-1945). Farmers raised grain and livestock to help meet the food needs of the Allies. Mining and manufacturing increased with the production of war goods.

In 1947, petroleum and natural gas were discovered at Leduc, near Edmonton. The discoveries led to widespread industrialization that changed Alberta's economy. The province owned most of the mineral rights in the land and received income from leases, rentals, and *royalties* (shares of the profits). Alberta used the money to expand its hospitals, roads, schools, and other public works. In 1957, the province paid its citizens a dividend from its oil income. Every adult who had lived in Alberta for at least five years received $20. In 1958, the provincial government paid a dividend of $17.50.

In 1954, for the first time, the combined value of Alberta mining and manufacturing became greater than that of agriculture. As industrialization increased, thousands of workers came to Alberta from other provinces, Europe, and the United States. Alberta's population increased greatly in the late 1950's and became mostly urban instead of rural. In 1945, less than a fourth of the people lived in Calgary or Edmonton. By 1966, about half the people lived in those two cities.

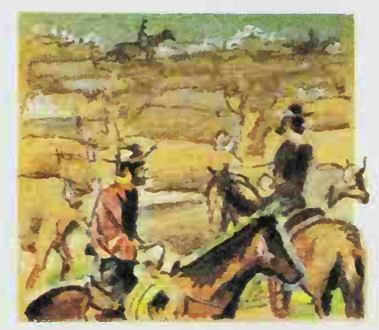


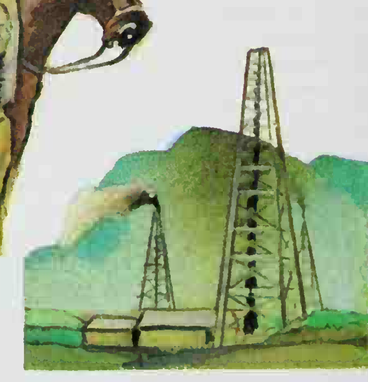
In 1958, James Gladstone of Alberta became the first Indian in the Canadian Senate. His appointment had been recommended by Prime Minister John G. Diefenbaker.

In 1962, coal production in Alberta dropped to a record low. The coal industry had begun to decline in the 1950's. For example, railroads switched from coal to diesel fuel as diesel locomotives replaced steam engines. Also, natural gas and fuel oil replaced coal in many heating systems. But in 1967, Japan became a new market for coal, and coal production started to increase.

Historic Alberta

Sir Alexander Mackenzie left Fort Chipewyan in 1789 on an expedition in which he discovered the Mackenzie River, the longest river in Canada.





Missionaries in Alberta during the mid-1800's converted many Indians and *métis* (people of mixed white and Indian descent) to settled ways of life on farms and in permanent homes.

The North-West Mounted Police came to Alberta in 1874. The Mounties drove liquor traders and outlaws from the region.

Ranching began in the 1880's when Montana ranchers drove their cattle across the Canadian border to the pasturelands of southern Alberta.

Oil and natural gas discoveries in Turner Valley in 1914 led to the development of a petroleum and natural gas field that is still productive.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Alberta

1670 King Charles II of England granted trading rights in the Alberta region to the Hudson's Bay Company.

1754-1755 Anthony Henday of the Hudson's Bay Company explored the Alberta region.

1778 Peter Pond of the United States established a trading post near Lake Athabasca.

1840 Robert T. Rundle became the first missionary in the Alberta region.

1874 The North-West Mounted Police established Fort Macleod.

1876-1877 Indians signed two treaties surrendering central and southern Alberta to the Canadian government.

1883 The Canadian Pacific Railway (now CP Rail System) reached Calgary.

1905 Alberta became a province on September 1.

1914 A major oil discovery was made in Turner Valley.

1921 The United Farmers of Alberta, a new political party, came to power.

1935 The Social Credit Party, another new organization, took over the Alberta government.

1947 The discovery of oil at Leduc started widespread industrialization in Alberta.

1954 The combined value of Alberta's mining and manufacturing exceeded that of agriculture for the first time.

1967 Alberta's first plant to remove oil from bituminous sands began operation.

1971 The Progressive Conservative Party came to power, ending 36 years of rule by the Social Credit Party.

1988 The Winter Olympic Games were held in Calgary.

In 1967, Alberta's first plant to remove oil from the bituminous sands of the Athabasca River Valley was completed. The Alberta "resources railway" went into operation in 1969. This 235-mile (378-kilometer) line extends from Grande Prairie to Brûlé. It opened undeveloped land in northern Alberta so that industry could reach mineral deposits and timber. The Alberta portions of the Trans-Canada Highway and the Yellowhead Highway also were completed during the 1960's.

In 1971, voters gave control of Alberta's government to the Progressive Conservative Party, ending 36 years of Social Credit Party rule. Peter Lougheed became premier. He resigned in 1985. Donald R. Getty, a Progressive Conservative, succeeded Lougheed as premier. Getty resigned in 1992, and the Progressive Conservatives chose Ralph Klein as the new party leader and premier.

In the 1970's and early 1980's, Alberta experienced great industrial expansion. The province's vast oil deposits have attracted many new industries, and thousands of people from other parts of Canada have come to Alberta to find jobs in the new industries. A second plant to remove oil from Alberta's bituminous sands opened in 1978. This plant is the largest industrial complex ever built in Alberta.

Recent developments. Calgary and Edmonton grew rapidly due to the expansion of retail trade, tourism, and other service industries. The 1988 Winter Olympic Games were held in Calgary. Calgary also became the headquarters of the Reform Party of Canada, founded in 1987. The Reform Party called for more attention to the western provinces and reform of Canada's constitution to create an elected Senate. The party grew rapidly. In the 1993 national election, it won 52 seats in the Canadian House of Commons. In the 1997 election, it won the second largest number of seats and as a result became the official opposition. In 2000, Reform members voted to dissolve the party and join a new conservative party called the Canadian Reform Conservative Alliance. The new party, commonly known as the Canadian Alliance, then became the official opposition in the House of Commons. G. Peter Kershaw and Roderick C. Macleod

Alberta, University of, is a government-supported, coeducational university in Edmonton, Canada. The university has undergraduate and graduate programs in agriculture and forestry, arts, business, dentistry, education, engineering, home economics, law, library science, medicine, nursing, pharmacy, physical education, rehabilitation medicine, and science. Its School of Native Studies offers programs that focus on issues affecting Canadian Inuit (formerly called Eskimos) and Indians. The university has a French-language faculty (Faculté Saint-Jean), which offers degree programs in arts, science, and education.

The provincial legislature of Alberta established the university in 1906. The school opened in 1908.

Alberti, *ahl BEHR tee,* **Leon Battista,** *lay OHN baht TEES tah* (1404-1472), was an Italian Renaissance architect, painter, and scholar. He spent his early years studying ancient Greek and Roman civilizations. During this time, he gained a reputation as a humanist and learned

Latin scholar as he wrote two influential books, *On Painting* (1435) and *On Architecture* (begun in the 1440's). The work on painting was the first scientific study of *perspective* (representing objects on a flat surface to give the illusion of receding distance).

From 1450 until his death, Alberti concentrated on architecture. His best-known buildings include the church of San Francesco (1450) in Rimini and the Rucellai Palace (1452) in Florence, as well as the *facade* (front) of the church of Santa Maria Novella (about 1456-1470) in Florence. Another of his masterpieces, the church of Sant' Andrea in Mantua, was completed in 1494, after his death. Alberti was born in Genoa. J. William Rudd

Albertus Magnus, Saint (1206?-1280), was a German-born Christian theologian, philosopher, and scientist. His importance lies in his awareness of the difference between theology and philosophy and between revealed truth and experimental science. He believed that different areas of knowledge follow different sets of laws and require different methods of investigation.

Albertus was advanced for his time in his knowledge of the sciences. He wrote about many scientific subjects, including astronomy, chemistry, geography, and physiology, using his own scientific observations. He devoted much of his time to popularizing the writings of the ancient Greek philosopher Aristotle. Albertus wrote a large number of commentaries on Aristotle's philosophy. These writings influenced Saint Thomas Aquinas, Albertus's most famous pupil, and other theologians known as scholastics (see **Scholasticism**).

Albertus Magnus was born into a noble family in Lauingen, near Ulm. He attended the University of Padua in Italy, where he joined the Dominican religious order in 1223. He studied and taught at a number of European universities but spent most of his time in Cologne, Germany. Albertus served as a high-ranking Dominican official in Germany, as a bishop, and as a representative of the pope. His feast day is November 15. Albertus is the patron saint of students of the natural sciences.

Marilyn J. Harran

Albigenses, *AL buh JEHN seez,* were a group named for Albi, a city in southern France. They were part of a sect called the *Cathari,* which flourished in parts of France, Germany, and Italy during the 1100's and 1200's. The Albigenses believed that the principles of good and evil continually opposed each other in the world. They believed that worldly things represented the evil force and that the human spirit was the only good. They taught that the spirit had been imprisoned in the body as punishment for sinning, and that the highest good was to free the spirit from the body. The Albigenses opposed marriage, bearing children, and eating meat and other animal products. They advocated suicide, especially by starvation.

The Albigenses grew in popularity until the church pronounced them heretics in the mid-1100's. But the nobility and the townsfolk supported them. The church conducted a crusade against the Albigenses in the early 1200's. Crusaders and the Inquisition gradually destroyed the Albigenses' power, though there were brief rebellions from time to time. By about 1350, the Albigenses had disappeared in Western Europe. Albino, *al BY noh,* is an animal or plant that is unable to produce *pigment* (coloring substance) in some or all of its organs. As a result, the animal or plant has abnormally light coloration. Albinism is caused by a change in the *genes* (units of heredity) and can be inherited. A person who is a *true* (complete) albino has milky-white skin, white hair, and pink eyes. The eyes are pink because the blood in the tiny vessels of the *iris* (colored part of the eye) shows through the transparent parts. In normal eyes, the iris hides the pinkness. Albinism occurs about once in every 20,000 births.

Albinism may vary from the complete absence of color to the presence of nearly normal amounts of pigment in some organs. Most white horses, chickens, ducks, and geese are only *partial* albinos because these animals have pigment in their eyes, beaks, or legs. Albino animals are rarely seen in the wild because their unusual coloration makes them inviting prey.

In many partial albino plants, only the flowers have no pigment. But some albino plants also lack chlorophyll and the leaves are also white. Such plants die unless they can get food from their surroundings, because plants need chlorophyll to make food. Lawrence C. Wit

Albright, Madeleine Korbel (1937-), served as secretary of state of the United States from 1997 to 2001. She was the first woman to hold the post. President Bill Clinton appointed her to the office. Albright had served as U.S. ambassador to the United Nations (UN) from 1993 to 1997. At the UN, she became known as an outspoken supporter of human rights and the use of UN peacekeeping forces in troubled areas.

Albright was born in Prague, Czechoslovakia (now Czech Republic). Her maiden name was Madeleine Korbel. Her father was a Czech diplomat. When Nazi German forces occupied Czechoslovakia in 1939, her father fled with his family to Yugoslavia and, eventually, to the United Kingdom. The family returned to Czechoslovakia in 1945 but fled again in 1948 when Communists took over the country. They settled in the United States.

U.S. Department of State

Madeleine Korbel Albright

Albright received a bachelor's degree from Wellesley College in 1959 and a doctorate in government from Columbia University in 1976. She was married to Joseph Albright, a journalist, from 1959 to 1983.

Albright served as a member of President Jimmy Carter's National Security Council staff from 1978 to 1981. She was a professor of international affairs at Georgetown University from 1982 to 1993. Andrew Bennett

Albumin, *al BYOO muhn,* also spelled *albumen,* is a sticky, gelatinlike substance. Its best-known form is the white of an egg. Albumin belongs to the class of foods called proteins (see **Protein**). The word is spelled *albumen* when it refers to egg whites, but *albumin* when re-

ferring to the general substance. The albumin of egg white is called *ovalbumin.* The albumin in milk is called *lactalbumin. Serum albumin* is the albumin in blood serum. It makes up over half of the protein in blood serum and helps stabilize other serum proteins. Some albumin is found in vegetable matter. All albumins contain carbon, hydrogen, nitrogen, oxygen, and sulfur.

Albumin becomes a solid mass when heated. If albumin is heated with a liquid, it either settles to the bottom as sediment or forms a scum at the top. The sediment or the scum collects foreign substances as it forms. Albumins are used to collect impurities from liquids in sugar refining, industrial dyeing, and making photographic chemicals. Kermit L. Carraway

Albuquerque, *AL buh KUR kee* (pop. 448,607; met. area pop. 712,738), is the largest city in New Mexico. It serves as a financial, industrial, trade, and transportation center of the Southwest. The city is also a leading center for energy, space, and defense research. For location, see **New Mexico** (political map). Albuquerque's heritage of both Pueblo Indian and Spanish culture gives the city a special atmosphere.

Description. Albuquerque, the county seat of Bernalillo County, covers about 168 square miles (435 square kilometers). The Albuquerque skyline includes a number of skyscrapers, but many low, flat-roofed, adobe houses help the city keep its Indian character. One of the city's landmarks, the Roman Catholic Church of San Felipe de Neri, served as a fortress that protected the early settlers during Indian raids. East of the city, the Sandia Mountains provide ski slopes, an aerial tram, and other recreational facilities. Albuquerque is the home of the Albuquerque Technical-Vocational Institute, the University of New Mexico, and Southwestern Indian Polytechnic Institute.

Federal nuclear weapon research and defense-related research rank as the chief industries in Albuquerque. Nearby Kirtland Air Force Base is a defense and energy research center. Sandia National Laboratories, on the Kirtland base, conducts energy research and development programs and is the largest employer in the state. Phillips Laboratory is also at the base and is one of the Air Force's largest weapons laboratories. Tourism is the city's most profitable nongovernment industry. Clothing and electronics factories, food-processing plants, and health care facilities employ many Albuquerqueans.

Government and history. Albuquerque has a mayor-council form of government. The voters elect a mayor and nine councilors to four-year terms.

Francisco Cuervo y Valdés, the governor of the Spanish province of New Mexico, founded Albuquerque in 1706. The community was named for the Duke of Alburquerque, a Spanish nobleman. The town became part of the United States as a result of the Mexican War (1846-1848). Albuquerque was incorporated as a city in 1891. It had about 3,785 people and served as a trading center for sheep ranchers.

After World War II ended in 1945, an increase in military spending created thousands of jobs in the nuclear research centers in and near Albuquerque. The city's population more than doubled from 1950 to 1960, rising from 96,815 to 201,189. An urban renewal program in the mid-1970's included a new convention center and a public library. In the late 1900's, the city completed expansions of the convention center and the Albuquerque International Airport. Kelly Brewer

For the monthly weather in Albuquerque, see **New Mexico** (Climate).

Alcan Aluminium Limited is one of the world's largest producers of aluminum and a manufacturer of aluminum products. Its headquarters are in Montreal, Canada. Alcan owns and operates companies in over 20 countries and maintains sales offices worldwide. These companies together are involved in all aspects of the aluminum business: bauxite mining, alumina refining, aluminum smelting, manufacturing, sales, and recycling. In addition, Alcan owns hydroelectric power plants that produce the energy required for aluminum smelting.

Industries served by Alcan include the four major markets for aluminum products: containers and packaging, transportation, building and construction, and the electrical industry. Its products include automotive parts, electric cables, chemicals, foil goods, and siding for buildings.

Alcan was formed in 1902 as a Canadian firm owned by the Aluminum Company of America (now Alcoa Inc.), a business based in the United States. In 1928, Alcan became an independent company and took control of most of Alcoa's business outside the United States.

Alcatraz, *AL kuh TRAZ,* was a famous federal prison on Alcatraz Island in San Francisco Bay. The name *Alcatraz* comes from a Spanish word meaning *pelican.* The island stands on 12 acres (5 hectares) of solid rock, and Alcatraz was often called The Rock. More than 1 mile (1.6 kilometers) of water separates it from the mainland. For the location of Alcatraz, see **San Francisco** (map).

Alcatraz Island became the site of the first permanent military fort on the West Coast in 1854. A military prison was added in 1861. In 1909, the wooden prison was replaced by a more modern concrete cell block. Alcatraz became a federal prison in 1934, built to confine some of the most dangerous criminals in the United States. In 1963, the federal government decided Alcatraz was too expensive to maintain and supply, and closed it. In 1972, Alcatraz became part of the Golden Gate National Recreation Area. Visitors may tour the prison.

James O. Finckenauer

Alcazar, *AL kuh zahr,* is the name usually given to palaces built by the Moorish rulers in Spanish cities. They sometimes had walls around them for defense, and were like fortresses. The one in Toledo, Spain, was destroyed during the Spanish Civil War (1936-1939). The Alhambra is perhaps the best-known alcazar (see **Alhambra**). William J. Hennessey

Alchemy, *AL kuh mee,* is a blend of pseudoscience, magic, and mystical philosophy. It was popular from the time of early Christianity until about 1700. Alchemists tried to change less costly metals into silver and gold. They also tried to find the *elixir of life* (a substance that would cure disease and lengthen life). They failed to find it, but their work in preparing and studying chemical substances helped the science of chemistry develop.

Some alchemists were only fakes. But others were learned people who had more philosophical goals. They

felt that if they learned how to make gold from lesser metals, they could also perfect other things. They considered gold the perfect metal because of its beautiful luster and its resistance to rusting.

Some alchemy was practiced in China and India before the birth of Christ. But it developed into a major system in Egypt during the next 300 years. The Greek-speaking scholars of Alexandria used it to try to explain how Egyptian artisans made things. Greek-Egyptian alchemy spread through Syria and Persia to the Arabs. It spread to Western Europe in the 1100's and 1200's.

Alchemists drew their theories of matter from the ancient Greeks. They believed that all matter was made up of a single, formless substance. Alchemists thought this substance became the four elements—earth, air, fire, and water—when combined with hot or cold and wet or dry. They thought they could change one substance into another merely by changing the balance of these elements, a process called *transmutation.* This theory led them to try producing gold from other metals. In the early 1500's, Swiss scientist Paracelsus tried to substitute sulfur, mercury, and salt for earth, air, fire, and water. Alchemists also searched for the *philosopher's stone* (a magical substance that was supposedly able to make the transmutation process easier).

Gold's lasting quality led many persons to believe that they would find the secret of long life or even immortality if they could discover how to make gold from lesser substances. The Chinese once believed that eating from golden dishes prolonged life.
